THE LANCET

A Journal of British and Foreign Medicine, Surgery, Obstetrics, Physiology,
Chemistry, Pharmacology, Public Health, and News.

IN TWO VOLUMES ANNUALLY.

VOL. CCXVII.

VOL. II. FOR 1929.

ONE HUNDRED AND SEVENTH YEAR.

EDITED BY

SIR SQUIRE SPRIGGE, M.D. CANTAB., F.R.C.P. LOND., F.R.C.S. ENG.,

AND

EGBERT MORLAND, B.Sc., M.B. LOND., M.D. BERNE.

LONDON
ISHED BY THE PROPRIETORS, THE LANCET LIMITED, NO. 7, ADAM STREET, ADELPHI, W.C., IN THE
COUNTY OF LONDON, AND PRINTED BY HAZELL, WATSON & VINEY, LTD., 52, LONG ACRE, W.C.2.

MCMXXIX.

INDEX TO VOLUME II., 1929.

REFERENCES AND ABBREVIATIONS

Readers in search of a given subject will find it useful to bear in mind that the references are in several cases distributed under two or more separate but nearly synonymous headings—such, for instance, as Brain and Cerebral, Heart and Cardiac, Liver and Hepatic, Child and Infant, Goitre and Thyroid, Diabetes, Glycosuria and Sugar, Eye, Ophthalmic, and Vision, Lunacy and Mental Disease, Arsenobenzol and Salvarsan, &c., &c., and that regional headings are more frequently used than pathological. Institutions and Corporations with the right to the prefix Royal will be found under that prefix, with the exception of Hospitals, which will be found under that heading; and Medical Societies, which are separately indexed under Societies. All Universities are indexed under the word University. (A.) = Annotation, (C.) = Correspondence, (N.I.) = New Inventions, (L.A.) = Leading Article, (M.L.) = Medico-legal, (M.T.T.) = Modern Technique in Treatment, (O.) = Obituary, (P.I.) = Parliamentary Intelligence, (R.) = Review, (R. and A.R.) = Reports and Analytical Records, (A.D.) = Clinical Interpretation of Aids to Diagnosis, and (N.P.) = New Preparations.

A Concordance of page numbers and dates of issue will be found at the end of the Index.

A

Abbott, Maude E., Clinical classification of congenital cardiac disease, 161
Abdomen, upper, place of surgery in lesions of, 903
Abdominal aortic aneurysm, case of (John K. Rennie), 923; cyst in a young child, an uncommon (A. H. D. Smith), 65; pain, significance of afferent impulses from the skin in the mechanism of (John Morley), 1240, discussion on, 226; surgery, some principles in (D. P. D. Wilkie) (Murphy oration), 803; tenderness and unnecessary operations, 740; (C.), 791
Abortion, contagious (C.), 853; among dairy cattle (P.I.), 1122; and Malta fever (P.I.), 307; prevention of, in cattle (P.I.), 1287
Abortion, early, and sterility, causes of, discussion on, 874; "incomplete," admission of to hospitals: should guardians be told? (A.), 1296
Accidents: are they a disease (A.), 856; in mines (P.I.), 1064; road, hospitals and, 504; (P.I.), 307, 950; 531, 619, 780, 962, 1035, 1289, 1290, 1395; stationary cars and (P.I.), 1066
Acclimatisation (A.), 622
Acid base balance in the blood, significance of (John R. Marrack) (A.D.), 512, 569
Acoustic tumours, diagnosis of, 1200
Actinic erythema, effect of radiant heat on the production of (F. Mackenzie Shattock and Mary D. Waller), 917
Actinotherapy: some clinical results of treatment (Albert Eidinow), 649
Adam, James, on treatment of asthma, 498
Addison, C., The Nation and its Food (R.), 54
Address, change of, our (A.), 676
Adenoids, medical and surgical aspects of, discussion on, 335
Adie, W. J., on diagnosis of frontal tumours, 662; on diseases of the pituitary body, 876
Adkins, retirement of Dr. George, 1392
Adler, Alfred, *The Case of Miss R.* (R.), 828
Adoption of children in Scotland (P.I.), 103
Africa and science (L.A.), 179
After-treatment of Operations (P. Lockhart-Mummery), 5th ed. (R.), 931
Agassiz, C. D., on the diagnosis of intrathoracic tuberculosis in children, 38
Air, clean (A.), 1271; evacuation of wounded by (A.), 1209; la cure d', 1074
Aircraft pilots, public, health of (P.I.), 1232
Airmen, standards of fitness in (A.), 511
Aitken, D. McCrae, on scoliosis, 284
Albuminuria of pregnancy, preventive treatment of, 501
Alcohol, methylated spirits and impure forms of, toxic effects of, discussion on, 124
Alexander, F. W., clean swimming baths (C.), 953; The new vaccination order (C.), 528
Alexander, Hanns, Was muss der praktische Arzt von der Chirurgischen Behandlung der Lungentuberkulose Wissen? (R.), 1118
Alexander, R. Charles, Accessory spleen with recurring torsion of its pedicle, 21
Alexander, Ruth, Stones, Hilltops, and the Sea (R.), 232
Alexandra Day Fund, record collection, 938
Alimentary tract, interpretation of radiograms of the (A. E. Barclay) (A.D.), 1158, 1210, 1272, 1322, 1377
Allen, I. M., and Worster-Drought, C., Thrombosis of superior cerebellar artery, 1137
Allbutt, Sir Clifford: A Memoir (Sir Humphry D. Rolleston) (R.), 1014
Almanack, Whitaker's, 1292
Almoners under the Local Government Act, 903
Alpine cures, assisted (A.), 343
Alport, A. Cecil, On Nephritis (R.), 1368
Aluminium silicate in the treatment of gastric ulcer (A.), 621
Alveoli of maxilla, implantation of epithelioma of, from primary growth in tongue (J. Bagot Oldham), 873
American Chemical Society monographs, 559; College of Surgeons: annual clinical congress (A.), 81; Medical Association: annual Convention, 353
Amino-Acids, Biochemistry of the (H. H. Mitchell and T. S. Hamilton) (R.), 559
Amœbiasis, hepatic, simulating cholecystitis (Ian Macdonald), 171; intestinal, symptomatology of (Philip Manson-Bahr and C. B. V. Tait), 1028
Anæmia, chlorotic, in the middle-aged (A.), 937; in school-children, diagnosis and treatment of, with special reference to hæmoglobin content (Nancy K. Gibbs), 550; (C.), 850; pernicious (A.), 563; importance of transfusion in the treatment of (Alexander Goodall and A. M. Calder), 1141; influence of liver treatment on mortality from (Peter L. McKinlay), 1086; insulin in the treatment of (L. von Varga), 761; nervous and mental aspects of (Douglas McAlpine), 613; stomach in (L.A.), 829; which resists liver treatment (A.), 935
Anaerobic bacteria, persistence of, in war wounds (R. J. V. Pulvertaft), 924
Anaerobiosis, objectionable, 208
Anæsthesia, The Art of (P. J. Flagg), 4th ed. (R.), 882; diffusion, of the peritoneal cavity, 1110, 1180; ethylene and oxygen, 337; gas and oxygen, in midwifery, 358; in rectal surgery, discussion on, 1258; Local, Practical (Robert Emmett Farr), 2nd ed. (R.), 1190; nitrous oxide, electrocardiographic study of human heart during and after (G. E. S. Ward and Samson Wright), 1184; rectal ether oil, with special reference to brain surgery, 558; spinal, with spinocain, 825
Anæsthetic for childbirth, another (A.), 833; local, another, 1074
Anæsthetic sickness, post-, ætiology and prophylaxis of (J. Ross Mackenzie), 1299
Anæsthetics, Handbook of (J. Stuart Ross and H. P. Fairlie), 3rd ed. (R.), 178; scientific administration of, 558
Analysis of Drugs and Chemicals (Norman Evers and G. D. Elsdon) (R.), 882
Anatomy and Physiology for Nurses, Elementary (P. M. Leslie) (R.), 1204; and the Problem of Behaviour (G. E. Coghill) (R.), 127; Comparative, Laboratory Manual for (Malcolm E. Little and Rudolf T. Kempton) (R.), 718
Anderson, John H., Cholecystography (A.D.), 400; Examination of the blood for bile-pigment (A.D.), 316
Aneurysm, abdominal aortic, case of (John K. Rennie), 923
Anglo-French Library of medical and biological science (C.), 410
Animal diseases, the study of, 191
Animals, experiments on (P.I.), 153; (A.), 206
Antenatal clinics (A.), 295
Anthracosis, miners and (P.I.), 368
Anthrax, reported cases of (P.I.), 1122
Anthropology and Modern Life (F. Boas) (R.), 178
Antivivisection meeting, disturbances at a (P.I.), 101, 202
Aortic disease, hard work and, 1218
Apicolysis, 1324
Apothecary, Mystery and Art of the (C. J. S. Thompson) (R.), 931
Appeal, doctor's successful (M.L.), 1325
Appendicitis, complications and mortality of (Richard Warren), 16; in pregnancy (A.), 510
Appendix, interpretation of radiograms of the (A. E. Barclay) (A.D.), 1322; shield (A. Ernest Sawday) (N.I.), 128
Appetising preparations, 531
Appetite, loss of, in childhood (A.), 32; (C.), 98, 140
Appointments, lists of, 50, 104, 155, 205, 259, 310, 360, 412, 532, 588, 641, 693, 747, 799, 854, 906, 960, 1010, 1071, 1124, 1179, 1236, 1292, 1342, 1397
April 1st, 1930 (A.), 1100
Arcolax (N.P.), 158
Argyria, case of, 1043
Arkwright, J. A., Virulence of the micro-organism in infective disease (Bradshaw lecture), 903

Armitage, George, and Gordon, John, in *collaboration with others, Use of a new* quinoline derivative in the treatment of infection, 968
Armour, Donald, Some of Lettsom's contemporaries, 855
Arrogance and ignorance in medicine (Sir E. Farquhar Buzzard), 695
Arrowroot: its medicinal and dietetic value (John Campbell), 311
Arsenic, the sale of (A.), 779 ; to minors (A.), 890
Arterial thrombi, multiple, 406
Arterio-venous fistulæ, congenital, 500
Artery forceps, improved (Hugh Donovan) (N.I.), 172
Artificial respiration, continuous, with maintenance of circulation for 12 hours after apparent death (J. Bagot Oldham), 497
Artificial silk works, health conditions in (P.I.), 1067
Asbestos dust, 230 ; workers and workmen's compensation (P.I.), 1068
Asherson, N., Note on hæmostasis in the *mastoid operation, 1359*
Aspiration during tonsillectomy (A.), 784 ; (C.), 951
Aspirin as a hirudicide (C.), 750
Assam's malaria problems and their solution (G. C. Ramsay), 1356
Association of Special Libraries and Information Bureaux, programme of, 589
Association of Surgeons of Great Britain and Ireland, offer of scholarship, 50
Asthma, and hay-fever (J. E. R. McDonagh), 271 ; bronchial, the mental factor in (M. K. el Kholy), 707 ; in children : value of sugar in prevention and treatment of (A. Arnold Osman), 1187 ; (C.), 1283 ; pathogenesis and treatment of, discussion on, 498 ; Research Council : new address, 694
"Asuero" treatment, the (C.), 638
Ataxias, familial, 1095
Athens, dengue in (A.), 135
Athletes, the after-history of (A.), 292
Atophan *administered by inunction*, 413
Auden, G. A., The age of marriage and of consent (C.), 689
Aural disease and bathing (A.), 182 ; *(C.), 256, 306, 357, 634*
Auricle of heart, enlargement of left (Francis Bach and T. S. Keith), 766
Auricular fibrillation in children (Harold Cookson), 1139
Auriscope, a new pocket electric, 208

AUSTRALASIA, CORRESPONDENCE FROM.—Australasian Medical Congress, 1007—Cancer research, what is being done in the Australias *towards*, 1007—College of Surgeons of Australasia, 352—Mackenzie, Dr. Colin, knighthood for, 576—New South Wales *Hospital Bill*, 577—*Pan-Pacific* Surgical Congress, 353—Queensland, hospitals in, 352—Radiation and living cells, 1007—Victoria, medical *education* in, *576*

Lectures

ON THE

PHYSIOLOGY OF GLYCOGEN

AND THE

RÔLE OF INSULIN AND EPINEPHRINE IN CARBOHYDRATE METABOLISM.

Delivered at the London Hospital

BY J. J. R. MACLEOD, M.B., LL.D. ABERD., D.Sc. (HON.) TORONTO, F.R.S.,

REGIUS PROFESSOR OF PHYSIOLOGY IN THE UNIVERSITY OF ABERDEEN.

LECTURE I.

(Delivered on May 14th.)

THE behaviour of the blood-sugar curve following the ingestion of soluble carbohydrates indicates that absorption must start at once. Under ordinary conditions none of this seems to occur in the stomach itself, as far as can be judged by chemical analysis, either of solutions of sugar left for some time in the viscus after ligation at the pylorus or of the chyme as this is discharged into the duodenum. Absorption of sugar takes place mainly in the upper levels of the small intestine, and different types of experiment have been employed to study the process. The oldest of these consists in placing known amounts of sugar in solution in isolated loops of intestine (Thiry-Vella) and then removing and analysing the contents after varying periods of time. The chief objection to this method depends on the fact that only an isolated portion of the entire gut is employed, an objection which is overcome in the method recently introduced by Cori and Cori,[1] in which the entire gastro-intestinal tract of small animals, such as the white rat, is used. The animals, kept for some time previously on a standard diet, are starved either for 24 or 48 hours, after which 2 or 3 c.cm. of a strong solution of sugar is placed in the stomach through a small flexible catheter passed by way of the mouth. The rate of absorption is ascertained by subtracting, from the amount of sugar that was given, the amount found by analysis of the gastro-intestinal contents after killing the animals at varying periods. Cori and Cori state that, when sufficient is given, the amount of sugar absorbed is constant from hour to hour, at least up to four hours, and they define as the coefficient of absorption that number of grammes of sugar absorbed per 100 g. of body-weight per hour. This is characteristic for each sugar, but it varies according to the time the animal was starved *prior* to giving the sugar. *It is independent* of the strength of the sugar solution.

For the monosaccharides the coefficients are given as follows: After 48 hours' starvation *d*-galactose 0·106 g., *d*-glucose 0·178 g., *d*-fructose 0·077 g., *d*-mannose 0·034 g., *l*-xylose 0·028 g., and *l*-arabinose 0·016 g. After 24 hours' starvation the coefficient for glucose is 0·206 g. These figures show a high degree of selectivity, dependent not at all upon molecular weight but markedly so on the structure of the molecule. Thus, the pentoses are absorbed at about one-eighth the rate of the better-known hexoses, and the slight stereoisomeric difference between glucose and mannose makes a marked difference. These results stand out in sharp contrast with those obtained for the rate of absorption from the peritoneal cavity, as determined on mice by C. F. Cori and Goltz.[2] In this case the sugar was absorbed at a diminishing rate with time, indicating that the concentration affects the process, and different sugars were absorbed at equal rates. When injected intravenously, different sugars were also found, by analysis of the so-called free sugar of the tissues, to be absorbed very rapidly and at equal rates into the liver and into the muscles, although it took a shorter time for equilibrium between blood and liver to be attained than between blood and muscles dependent probably on differences in the richness in blood-supply.[3]

I have only instanced a few of the numerous results which these workers have placed on record, but they are sufficient to show that the intestinal mucosa is endowed with a very highly specialised selective action, which is absent in the case of certain other absorbing membranes. It seems remarkable that bacterial decomposition should not account for a measurable fraction of the sugar which disappears from the intestine during four hours and that the concentration of the solution should not affect the rate of absorption. Cori and Cori state that no significant amount of glucose disappears when a solution of it is placed in the excised gastro-intestinal *tract kept in isotonic saline solution at body temperature* for four hours. At my request Magee and Auchinachie have repeated this experiment and on one or two occasions have been able to recover all the glucose. On other occasions, however, there were considerable deficits which may have been due to bacterial destruction or to incomplete washing of the sugar out of the walls of the gut. Is it not possible also that bacterial action might occur in the intact intestine, in situ, but be retarded or absent in the excised one? Corroboration or otherwise of the accuracy of the coefficients of absorption as given by Cori and Cori for different sugars would be most important since their subsequent researches, in which they compare the amount of sugar absorbed, on the one hand, with the amount that can be accounted for by combustion and glycogen formation on the other, depends on it. One also wonders whether the higher coefficients of absorption observed for rats starved 24 hours, as compared with those starved 48 hours, may not have been due to greater bacterial destruction in the former case. It may be added that another of the Cori's conclusions—namely, that the rate of absorption is independent, within wide limits of the sugar concentration, has been called in question by Pierce, Osgood, and Polansky.[4] These workers found, on repeating Cori's experiments, that the rate of absorption was less between the second and third hours than between the first and second. In a reply to this criticism, however, Cori, Cori and Goltz[5] point out that Pierce, &c., did not feed enough sugar to let the absorption proceed for three hours.

Although there may be reasons to doubt the reputed extreme accuracy of the coefficients, it is nevertheless certain that the striking differences observed cannot be mainly attributed to differences in the extent of destruction of the sugars by the bacteria of the intestine. That the hexoses are more readily absorbed than the pentoses has been confirmed by Magee and myself[6] in experiments of a different type from those of the Cori's. In these, we measured the rates of diffusion of equimolecular solutions of various sugars through the walls of isolated loops of rabbit's intestine, kept alive by being suspended in oxygenated Tyrode's solution.

The different sugar solutions were placed in neighbouring loops of approximately equal weight and small portions of the outside solutions were pipetted off at intervals for determination of the reducing power by the Shaffer-Hartmann method. It was found in preliminary experiments that diffusion proceeds through pieces of gut which had previously been killed, either by heat or by the action of sodium fluoride, much more rapidly than through the living gut and that, in equimolecular concentration, pentoses diffuse more rapidly than hexoses, being dependent solely on the concentration of the sugar solution. Through living segments on the other hand, glucose diffused as quickly as pentose, or in some experiments more quickly.

It is undoubted, therefore, that the intestinal mucosa absorbs hexoses more rapidly than pentoses, and I cannot resist wondering whether the former undergo some change in the process. That the blood-sugar may consist of some form of glucose which differs in configuration from a mixture of the α- and β-glucoses, has been suggested by various authors, without any evidence being adduced to support the suggestion. It has, however, generally been assumed that this change, if it occurs, depends either on a preliminary conversion of glucose into glycogen or on the action of some hormone such as insulin, but is it not possible, as has been hinted at by various writers, that some change actually occurs in the glucose molecule while it is passing through the intestinal mucosa?

INTERPRETATION OF CHANGES IN THE BLOOD-SUGAR.

It is not my intention here to enter further into the various interesting questions regarding intestinal absorption which await investigation by these methods, but, confining ourselves to the sugars, it may be of interest if I refer to the significance of the results which we have just been considering in connexion with the behaviour of the blood-sugar following carbohydrate ingestion. When this is observed in man at short intervals, after moderately small amounts of sugar have been taken in the post-absorptive state, very constant results are obtained, and it is considered that any unusual heightening or lengthening of the curve, which is obtained by plotting percentages of blood-sugar against time, is indicative of a diabetic tendency. Useful though this method may be as a clinical test, it should always be borne in mind that numerous factors enter in to influence the behaviour of the curves, for not only does this depend on the rate of intestinal absorption of the sugar, which again is dependent on many factors, but also on the rate at which the tissues utilise the sugar that is absorbed. This disposal may be influenced in several ways, and there is accumulating evidence to show that these are largely controlled by the concentration of insulin in the blood.

How complicated the matter really is may be illustrated by comparison of the blood-sugar curves following ingestion of fructose and glucose. The former sugar has a very small influence as compared with that of the latter and this is used clinically as a test of the efficiency of the liver, on the assumption that the difference depends on a rapid polymerisation of the fructose to glycogen in this organ. If Cori and Cori's results on rats apply in the case of man—namely, that fructose is absorbed at only half the rate of glucose—then it is possible that this may in itself account for the smaller influence which fructose has on the curve. But the problem is really a complex one, since galactose was found by the Cori's to be absorbed even more rapidly than glucose, whereas this sugar, according to Folin and Berglund,[7] has little influence on the blood-sugar level.

When the intestinal factor is eliminated, by injecting intravenously at a slow continuous rate, the tolerance towards sugar may be determined by observing whether any is excreted in the urine. By this method Sansum, Woodyatt, and Wilder[8] showed, several years ago, that 0·85 g. of glucose could be tolerated per kg. body-weight and per hour, both in man and laboratory animals. In the white rat (under amytal anæsthesia) and in the mouse, however, Cori and Cori state that the tolerance is three times as great (2·5 g. per kg.), except during the summer months when there is a lowered tolerance (1·6 g. per kg.) and this was found to be related to the development of a certain degree of ketonuria.

THE GLYCOGEN OF THE LIVER.

Physiologists have become so familiar with the view that the glycogen of the liver represents a storage form of carbohydrate, that they have neglected to take notice of many well-established facts which indicate that it is also, in a sense, an internal secretion. As Cramer[9] has pointed out, this was the original conception of Claude Bernard, who believed glycogen to be produced out of protein, not denying, however, that it is capable also of being formed out of absorbed carbohydrate. And at the outset of a discussion of the significance to be attached to variations in the amount of glycogen which can be found in the organ after death, it is important to recognise that this is only a balance between processes of production and loss and may be no measure therefore of the rate at which these processes are proceeding during life; as Cramer puts it, "one should look upon the glycogen of the liver dynamically, and not, as has been done, statically as a mere store of excess of carbohydrate."

When food is withheld, the amount of glycogen in the liver rapidly becomes decreased and then increases again. In the white rat, for example, Barbour, Chaikoff, Macleod, and Orr[10] found the average percentage, in 24 hours after withdrawal of food, to be 0·16 per cent. (average of 48 rats), whereas after 48 hours it was 0·32 per cent., and these figures have, in general, been confirmed by Cori and Cori. Hershey and Orr[11] found that a steady increase occurs during later periods of starvation, although the values for individual rats were observed to be less constant than for those killed after 24 or 48 hours. The increase can be seen from the following results of an observation in which three rats were killed at each period.

	Per cent.
After 72 hours' starvation	0·21 and 0·21
" 96 " "	0·65, 0·23 and 0·34
" 120 " "	0·42, 0·23 and 0·92
" 144 " "	0·78, 0·78 and 0·78

These results confirm those previously obtained by Pflüger on the dog in showing that a new formation of glycogen, or gluconeogenesis, is occurring in the liver during starvation. Protein and fat are the only known sources for this glycogen, and there are many who believe that the former is alone available, but this question does not concern us here.

Although it has been recognised for some time that starvation alone does not cause all the liver glycogen to disappear, it is usually taught that this occurs when the fasting animal is made to perform muscular exercise. But Hershey and Orr have been unable to confirm this. Again using the white rat, these workers induced muscular exercise, either by causing the animals to work until exhausted on a treadmill, or by making them swim, with short intervals of rest, in cold water, every precaution being taken to see that the time elapsing between termination of the exercise and removal of the liver was as short as possible. The preliminary fasting period was 24 hours and, in order to rule out all chances of error, a litter mate, left fasting at rest, was used as a control in each observation. The following are typical results:

	Glycogen per cent.
After 2 hours' exercise the liver contained	0·16
And that of the control rat	0·16
After 3 hours' exercise the liver contained	0·16
And that of the control rat	0·20
After 6 hours' exercise the liver contained	0·14
And that of the control rat	0·14

The liver of a rat which ran on the treadmill for 23 hours still contained 0·20 per cent. glycogen.

In none of these experiments was it possible to induce any greater reduction in liver glycogen by muscular exercise than by fasting alone. Corresponding results were obtained in the rats which were made to swim in cold water. Thus, in two rats that were in the water off and on for a period of 90 minutes, following a fast of 24 hours, the percentages of glycogen were 0·17 and 0·18.

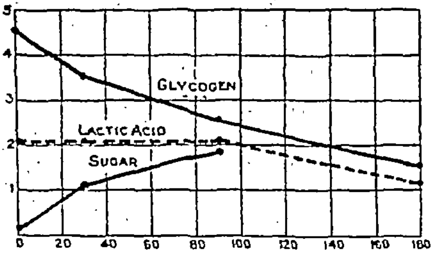
Before concluding that it is impossible to rid the liver of glycogen by starvation combined with muscular exercise, it was decided to repeat the observations by what is usually considered to be an infallible method for this purpose—namely, by inducing strychnine convulsions while the animal is under artificial respiration. In three rabbits, deprived of food for 48 hours and then injected with sufficient strychnine to induce convulsions for periods of 38, 44, and 57 minutes, the liver contained 0·09, 0·06, and 0·08 per cent. of glycogen respectively, and in other observations of a similar nature still larger amounts were found. These results show that the glycogen of the liver is of much greater metabolic significance than is implied in the notion that it represents a storage form of carbohydrate.

In pathological conditions, also, it is questionable whether all traces of glycogen ever disappear from the liver; at least we have always succeeded in demonstrating its presence in the liver of completely depancreatised and fasting animals several days after they had been rendered diabetic by removal of insulin. Bordering on the pathological are those conditions established after repeated injection for a week or so of thyroid extract. Cramer and Krause[9] found that the glycogen in the liver became so far reduced, even when carbohydrate food was given during the thyroid injections, that its amount could not be estimated by the Pflüger-Bertrand method, and this has been confirmed by Kuriyama[11] and by Burn and Marks,[12] but probably some traces were present. It is important that it is only after the thyroid hormone has been repeatedly injected for some time that the glycogen almost disappears. During earlier stages no change occurs in the actual amount of glycogen in the liver, although it appears to be more readily convertible into sugar, as judged from its behaviour after injecting insulin or epinephrine. Thus, it requires very large doses of insulin to lower the blood-sugar, but only very small ones of epinephrine to raise it. These results suggest that it is not alone the percentage of glycogen in the liver that determines the readiness with which this organ may discharge sugar into the blood, but also the sensitivity of the glycogenolytic mechanism.

Of course, it would be dangerous to affirm that the liver can never be entirely cleared of glycogen, but for the present we must regard this substance as an essential intermediary in liver metabolism.

Considerable attention has in the past been given to the disappearance of glycogen from the liver which occurs immediately after death—the so-called post-mortem glycogenolysis—but it is not my intention to enter into this subject further than to allude to an interesting difference between the process in the liver and that in the muscles. The actual amount of glycogen which disappears in a unit of time under similar conditions is very much alike in both cases, but the substances which are formed from it are different. As the glycogen disappears from the liver, free sugar increases and there is no increase in lactic acid (see Fig. 1), whereas in muscle there is no increase in free sugar but lactic acid ultimately accumulates almost in proportion to the glycogen which has disappeared (Macleod and Simpson[14]). (Compare with Fig. 3.) We will again have occasion to refer to the significance of these results.

FIG. 1.



Showing disappearance of glycogen from the liver with increase of free sugar and decrease of lactic acid. (Lactic acid in parts per 10,000; glycogen and sugar in parts per cent.)

Accumulation of Glycogen in the Liver.

Turning now to the conditions which cause glycogen to accumulate in the liver, we again find that the storage hypothesis is entirely inadequate. Perhaps the results which show this most convincingly are those obtained, first of all by Pollak[15] and later by Markowitz,[16] as a result of injecting epinephrine repeatedly into animals after the glycogen of the liver had been reduced to a minimum, through fasting and strychnine. Each injection of epinephrine was followed by hyperglycæmia, and after the injections had been repeated many times during several days, the liver was found to contain considerable amounts of glycogen. This is shown in Table I.

We shall see in the succeeding lecture that Cori and Cori have attempted to explain this result as dependent on a transfer, or shift, of glycogen from muscles to liver, but even if this were to account for the glycogen accumulation following one injection of the hormone, it certainly could not do so for that remaining after repeated injections during several days.

TABLE I.—*Glycogen in Rabbits after Repeated Injections of Epinephrine.*

No.	Days(a)	Glycogen (per cent.).			Remarks.
		Liver.	Heart.	Muscle.	
7	6	0·33	0·330	0·14	Prior to injection withheld for 5 days and strychnine injected.
28	6	0·16	0·234	0·13	Ditto (4 days).
8	5	0·98	0·14	0·19	Ditto (5 „).
22	9	1·05	0·100	0·20	Ditto (5 „).

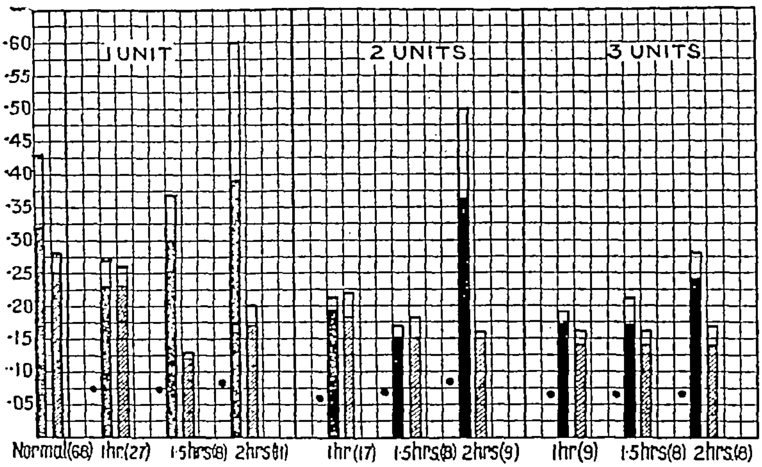
(a) Days on each of which from 3–6 c.cm. 1–1000 adrenalin injected in frequent doses.

But although epinephrine stimulates the internal secretion of glycogen in fasting animals it is generally regarded to do the opposite—namely, to hasten its breakdown when given to animals with large stores of glycogen in the liver. This latter belief is mainly based on experiments by Ritzmann, but Olmsted and Coulthard[17] found it very difficult in the spinal cat to obtain corroborative evidence. It was only when the preparation was allowed to stand for some hours after decapitation, so as to get rid of all anæsthetic from the blood, that they were able, by actual measurement of glycogen in small pieces of liver, to demonstrate that a decrease in percentage occurred as the blood-sugar rose. In view of these results, this hormone must be regarded as having a reversible action, causing glycogen to be deposited in the liver when none is there and to be broken down when abundance is already present. The other hormone which most definitely has an influence on carbohydrate metabolism—namely, insulin—exhibits similar reversible effects, although the procedures necessary to demonstrate them are different in detail. Thus, when insulin is given without food to fasting white rats it first of all causes the glycogen content of the liver to become reduced, but this is followed by an increase, provided a convulsive dose has not been given. This is shown in the accompanying chart (Fig. 2) and will be referred to again when we come to consider the action of insulin. Reversible effects of insulin are also seen by comparing its action on normal and diabetic animals. When it is given along with food to normal animals, glycogen is always deposited in the liver much more slowly than after food alone, as will be shown later, whereas there is an invariable and often a marked increase in liver glycogen when insulin is injected into diabetic animals, both when food is also given and when it is withheld.

Although the observations which we have just considered, as well as those of Cramer, show quite clearly that glycogen must be produced in the liver cells out of non-carbohydrate material, by some sort of secretory process, it must not be lost sight of that it can also be deposited in them by condensation of glucose, and other hexose monosaccharides, carried to the viscus by the blood. At least, this is the simplest way by which the gradual increase in glycogen percentage can be explained when food rich in carbohydrate is fed to a previously fasted animal. In our observations of this type on white rats it was noted that the increase in glycogen was usually less marked during the first hour or so after feeding than later, the maximum, of about 4 per cent. being reached in approximately four hours. This retarded onset in glycogen deposition may possibly depend upon an unpreparedness of the liver to condense the sugar;

it cannot be due to inadequacy of a supply of blood-sugar, since this begins to mount within a few minutes of feeding the rats and, in our experiments, had reached the peak in at least one hour after feeding, and probably much earlier.

FIG. 2.



Influence on glycogen, in white rats, of varying amounts of insulin injected after 48 hours' fasting. Ordinates, per cent. glycogen; abscissa, times of killing after injection; black columns, liver; cross-hatched columns, muscles. Numbers in brackets give number of animals averaged in each case, and the unshaded portion of each column, the percentile error. Black dots, blood-sugar percentage.

Many factors may come into play in the formation of glycogen in the liver and some of these, such as the presence of insulin and epinephrine, we will discuss more fully later. Others concern the chemical structure of the carbohydrate present in the circulating blood, but inasmuch as the observations have been mainly restricted to the liver of cold-blooded animals they do not concern us here. A decided increase in glycogen occurs in the liver in the spinal cat, especially during the first hour or so after decapitation. Olmsted and Coulthard,[17] who discovered this, could give no suggestion as to what the precursor of the glycogen might be, although the blood-sugar, meanwhile falling, was no doubt partly responsible. Recently Cori and Cori,[18] finding that *d*-lactic acid readily forms glycogen in the liver when given to rats, by feeding or injection, have attributed the result to *d*-lactic acid coming from the muscle glycogen. The only difficulty in this explanation is that the glycogen remains unchanged in the muscles of the spinal cat, according to Best, Hoet, and Marks.[19]

THE GLYCOGEN OF THE MUSCLES.

Turning now to the glycogen of muscle, which has come to occupy so important a place in physiology, let us consider first of all the question of its formation. This seems to be mainly dependent on the sugar of the blood, which may be derived either from the breakdown of liver glycogen or more directly from absorbed glucose. Some puzzling facts have recently been brought to light concerning the influence of the liver. After this organ has been removed in the dog the muscle glycogen steadily declines, Mann and Magath[20] finding that it was on an average 0·3 per cent. immediately after the hepatectomy, and 0·15 per cent. four hours later. Curiously enough, this diminution does not occur when the liver is practically eliminated from the circulation in the spinal cat, by ligation of the portal blood-vessels along with removal of the remaining abdominal viscera. In both groups of experiments the percentage of blood-sugar falls, but it is possible that it does so relatively less rapidly in the eviscerated preparation, on account of a leakage of sugar from the liver through the patulous hepatic veins. But even if we allow for this leakage of sugar, it is difficult to account for the constancy in the glycogen of the muscles of the eviscerated preparation since, though not visibly contracting, they are meanwhile producing heat at the rate of at least 2 calories per kg. of body-weight and per hour. If the immediate fuel for this combustion is the glycogen of the muscles, as is the present-day teaching, then we must imagine that glycogen is being built up in each muscle at a rate which is just exactly the same as that at which it is being broken down, and that its source is, in large part, the sugar which is escaping into the blood from the liver, since the total amount of sugar originally present in the blood is far from sufficient to account for the energy expended.

Best, Hoet, and Marks[19] have shown that when glucose is added to the blood of the eviscerated preparation, no glycogen is formed in the muscles unless when insulin is injected along with the sugar. On the other hand, Choi[21] has shown that when the glucose injections are made into an animal from which the abdominal viscera have not been removed, glycogen is formed in the muscles, this being dependent upon the insulin secreted by the pancreas, since no glycogen formation occurs in animals from which this organ, but not the liver, has been removed some hours preceding hepatectomy. This is shown in Table II. It is no doubt for the same reason that the fall in glycogen in the muscles of hepatectomised dogs is prevented when glucose is injected intravenously, but according to Mann and Magath[20] much more glucose must be injected to accomplish this than the 0·25 g. per kg. per hour that suffices to maintain the blood-sugar at its normal level. Although these results show that glycogen formation can occur in the muscles in the presence of insulin, this does not mean that insulin is essential for the process, since glycogen is formed in the muscles of diabetic (depancreatised) animals. Thus Chaikoff[22] found the average percentage of glycogen in the muscles of dogs on the third day of acute diabetes (caused by withdrawal of insulin from previously depancreatised animals) to be 0·425 per cent., and on the fifth day 0·350 per cent. During this interval at least 2 calories per kg. an hour were used, so that a dog of 7 kg. (about the average of the animals used) would have expended at least 2 × 7 × 48 = 672 calories, representing about 160 g. of carbohydrate, in the two days, and for this, large quantities of muscle glycogen must have been formed, unless we assume that other substances than glycogen can serve as the fuel for energy production in muscle. We cannot say what factor may be responsible for glycogen formation in the muscles when there is no insulin available in the body, but it would seem most likely that it depends in some way on the liver. In other words, the material which is

TABLE II.—*Effect of Injection of 3·5 g. Glucose on Glycogen of Muscles in Spinal Cat.*

—	Average per cent. glycogen in muscles.		No. of expts. averaged (3 muscles in each).

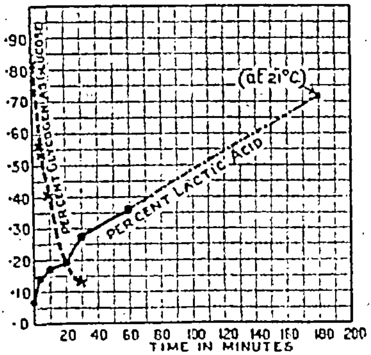
used for glycogen formation in the muscles when no insulin is present may be glucose that has passed through a glycogen stage in the liver or has been manufactured in this viscus, or even in the muscles themselves, by a process of gluconeogenesis.

In so far as experimental evidence goes at present, however, the only way by which glycogen can be formed in the muscles of an eviscerated preparation is by injection of glucose in the presence of insulin. Fraser and I, using this preparation, have tried to find some carbohydrate derivative which would form glycogen in the muscles independently of this hormone, but without success except in one experiment in which di-hydroxyacetone was injected.

FIG. 3.



Decrease of glycogen and increase of lactic acid in mammalian muscle after death.

These substances have been fructose, r-sodium lactate, di-hydroxyacetone and glycogen hydrolysed by diastase, so as to form a mixture of dextrine and sugar. Solutions of them were injected continuously into the femoral vein during periods of several hours without causing the glycogen percentage of certain selected muscles of the fore and hind legs to become increased over the percentages found present in the same muscles excised before the injections began. An unsuccessful attempt was also made in these experiments to demonstrate a possible influence of the liver, by adding to the glycogen solutions extracts prepared from this organ by faintly acidulated water.

During fasting, in the white rat the muscle glycogen steadily declines for between 24 and 48 hours, after which it remains at a constant level at least for several days. When food is given at this stage the glycogen does not, as a rule, begin to increase until after an hour or so (as illustrated in Fig. 5, Lecture II.), although absorption of glucose has been for some time sufficient to raise the blood-sugar level considerably. This latency may be dependent on inability of absorbed glucose to form muscle glycogen, either until after it has passed through a glycogen stage in the liver or until it has stimulated the pancreas to secrete sufficient insulin so as directly to affect the process of glycogen formation in the muscles. In connexion with the former possibility, it is to be remembered that glycogen formation in the liver itself does not increase much during the first hour after sugar is given to fasting animals.

The impossibility of detecting glycogen formation in mammalian muscle which has been isolated from the influence of the abdominal viscera stands out in contrast with the glycogen formation which Meyerhof and others have demonstrated to occur in isolated frog muscle under certain conditions. This result, like others, makes it probable that there are considerable differences in the chemical mechanism of amphibian, as compared with mammalian, muscle.

Breakdown of Glycogen in Muscle after Death.

Before turning our attention to the question of glycogen utilisation in the muscles, it may be well here to refer to a series of observations regarding the behaviour of glycogen in mammalian muscles after death. It is usually assumed that glycogenolysis sets in immediately, but although this is the case when the muscle has been injured, we have found that the contrary is the case for undamaged muscle. The most rapid onset of glycogenolysis occurs when the muscle is first of all frozen and then ground up into small pieces. Thus Simpson and I found,[14] when we allowed the frozen muscle powder to thaw, that practically all glycogen disappeared from it in from 20–30 minutes. Even when the temperature after thawing was not allowed to rise more than a few degrees above freezing-point, the disappearance of glycogen was very rapid, and it was also found that lactic acid did not increase nearly so quickly as the glycogen disappeared. These changes are shown in the accompanying curves (Fig. 3), which are taken from more recently performed experiments done along with Thomas. It will further be noted from these curves that lactic acid went on accumulating in the muscle suspension long after all the glycogen had disappeared. In the curve shown, the lactic acid failed to reach the amount represented by the glycogen to start with, but in other experiments it sometimes exceeded this. The irregularity of the result in this respect may indicate the operation of some as yet unknown influences on the change. The interpretation which we have put upon these results is that some substance is formed between glycogen and lactic acid, and it is possible that the presence of this in the muscle to start with accounts for the excess of lactic acid which was sometimes found after longer standing. We have been unable to demonstrate the nature of this intermediary substance. It is apparently not sugar since little increase could be detected in the reducing power of a 70 per cent. alcoholic extract of the muscle mixture by the time the glycogen had all disappeared. There was also no change in free phosphate, using the Doisy-Bell method, and we have been unsuccessful in correlating the disappearance of glycogen with breakdown of phosphagen. We suspect that this intermediary substance may be some carbohydrate, perhaps a trisaccharide, which is destroyed by 30 per cent. KOH and is insoluble in 70 per cent. alcohol. I have already alluded to the different results obtained with liver under similar conditions.

TABLE III.—*Percentile Change in Glycogen at Varying Intervals after Death.*

—	Time left after death.		Change per cent. in glycogen.			Condition of muscles.
			Sartorius.	Gracilis.	Gastrocnemius.	
	hrs.	mins.				
Rabbit.	—	40	−4·2	No change.	+10 h.c.	Soft, pink, irritable.
	2	—	−54	−10	+2 h.c.	Greyish, irritable.
	4	10	−84	−70	−63	Opaque, very slightly irritable.
Cat	2	30	−34	−14	−2·5	Irritable.

h.c. = higher than control.

As these researches were in progress, Orr and his associates noted that there was very little, if any, difference in the percentage of glycogen in the muscles removed from rats that had been dead an hour or so, as compared with that in muscles removed immediately after killing. This observation led to a special study by Miss Mackay[15] of the behaviour of glycogen in intact muscle, in which she compared the percentages in certain muscles removed under ether anaesthesia from one limb (in rabbits) with those of the corresponding muscles from the opposite limb removed at varying periods after death. The results are summarised in Table III. in which the changes in glycogen at the periods indicated after death are expressed as a percentage of the amounts present in the corresponding muscles immediately before death.

It can be seen that post-mortem glycogenolysis in intact muscle is very slow compared with that occurring in pulverised muscle, that its rate varies considerably in different muscles, and that the glycogen, instead of decreasing, may actually increase in amount. Incidentally, it was observed by Miss Mackay that the irritability of the muscles towards electrical stimulation persisted longer in those which had been dissected free from the surrounding tissues and kept moistened with gauze soaked in Ringer's solution than in muscles left in situ without any dissection. The onset of rigor was also delayed in the dissected muscles. The most noteworthy result was, however, the apparent increase in glycogen observed especially in the gastrocnemius muscles. Since this was not very marked, however, it might signify nothing more than a relative increase due to blood having drained out of the muscle after death. In more recent experiments which Fraser and I have performed, this possibility has been ruled out, since we did not remove the muscles from the left leg until immediately after death.

Rabbits killed either by chloroform or by stunning were used. Certain muscles were then dissected from the left leg, and after leaving the carcass for an hour at room-temperature, the corresponding muscles of the right leg were removed. Table IV. shows some of the results, and in this case these are given in actual percentages, as well as in percentile changes.

TABLE IV.

No.	Muscle.*	Glycogen. Per cent.		Percentile change + or —	Lactic acid. Per cent.	
		Left.	Right.		Left.	Right.
31	T.a.	0·69	0·83	+ 20	0·21	0·27

	G.	0·42	0·29	— 32	0·06	0·11

* The animals were killed by chloroform, but similar results were also obtained in those killed by stunning.

T.a. = tibialis anticus; G. = gastrocnemius.

The usual variability, both in the glycogen content of corresponding muscles in different animals and in that of different muscles in the same animal, is seen, but in only one animal was the percentage less in one hour after death in both of the muscles examined. It is possible that corresponding muscles of the two sides did not contain the same percentages of glycogen at the time of death, and this will require further investigation. In the light of observations on other animals than the rabbit it has been assumed that the percentages are alike. We also determined the percentage of lactic acid, using for this purpose the modified permanganate oxidation method after removal of sugar from an alcoholic extract of the muscle, by means of copper sulphate and milk of lime. An increase is evident in all cases, but no relationship can be detected between either the glycogen percentage to start with or the extent of the post-mortem increase in glycogen and the increase in lactic acid.

These results, which it may be stated are not dependent upon any changes in the water content of the muscles, suggest the presence of some hitherto unknown precursor from which both glycogen and lactic acid are derived. This must either break down first of all into glycogen, lactic acid being formed at an independent rate out of the general store of glycogen, or it must be a substance from which both glycogen and lactic acid are formed. In the former case, the substance would be a larger molecule than glycogen, whereas in the latter, it would be a smaller one and might be a lower dextrine or some poly-saccharide, perhaps a tri-saccharide. We have so far been unsuccessful in demonstrating any change in the free sugar of the muscle extractable by alcohol, but this may be because we used strong alcohol in preparing the extracts.

I have already referred to experiments by Simpson, Thomas, and myself in which it was shown that glycogen disappears from pulverised frozen mammalian muscle after thawing much more rapidly than lactic acid accumulates, and from which it was concluded that between the two some intermediary substance, possibly a tri-saccharide, must be formed. It is just possible that we are dealing with the same substance in both groups of experiments, but if this be the case then we must suppose that the agency for its conversion into glycogen becomes destroyed by freezing and pulverising the muscle. May it be because of destruction of the architecture of the muscle-fibre by the fine ice crystals which form in it when it is suddenly frozen, that the power of glycogen synthesis disappears?

Breakdown of Glycogen in Muscle during Life.

With regard to the breakdown of glycogen in mammalian muscle during life, very little is definitely known, at least for muscle which is under perfectly physiological conditions. That the percentage of glycogen remains unchanged for at least an hour after the blood pressure has been reduced to zero makes one wonder whether its failure to rise in the muscles of an eviscerated preparation, even when excess of glucose is present in the blood, may not indicate that a part of the glycogen-forming powers have disappeared, although they can be stimualted in the presence of an excess of both insulin and sugar.

It has been known for long that the glycogen becomes reduced when the muscles contract, and, of the older experiments, I need only recall here those of Manché[24] and Chandelon,[25] who compared its amount in the muscles of one leg, paralysed by cutting the nerve-supply, with those of the opposite leg in which there had been more or less activity. An experiment of this type more recently performed is that of Best, Hoet, and Marks,[19] who, by injecting convulsive doses of insulin into cats in which the sciatic nerve of one leg had been severed, found that the glycogen content of the paralysed muscles remained high, while it became very low in those undergoing contractions. Incidentally, it may be remarked, these results also show that the glycogen of one set of resting muscles cannot be drafted, by way of the circulation, to provide glycogen for an active set, even although the demands of the latter may be urgent. In the light of these results and also those obtained on isolated frog muscle, it is to be expected that glycogen will decrease when mammalian muscle is stimulated. Some results obtained by Miss Mackay will illustrate this.

In the decapitate cat three muscles were dissected from the left leg, and the corresponding ones of the right leg were then stimulated electrically, either through the nerve or directly. The extent of reduction in glycogen, calculated as a percentage of the amount originally present in the resting muscles, is shown in Table V.

Even a few moments of activity is seen to be associated with a decided reduction in muscle glycogen, and this becomes more marked as activity is maintained.

In these experiments the liver was still intact and it contained a rich supply of glycogen, owing to previous feeding of the animals with sugar. Had the liver been absent it is probable that the glycogen would have become more rapidly reduced by activity, and it was the original intention of the research to study this possible influence of the liver. With this in view Miss Mackay performed several experiments in which the muscles in animals with the liver intact and containing much glycogen were left at rest for an hour or so after stimulating them, but the extent to which the glycogen reappeared, as judged by comparison with the results shown in Table V., was very limited, if any really occurred. I have formed the impression, both from these experiments and from those more recently performed by Fraser and myself, that the failure to demonstrate decided glycogen formation in the muscles of the spinal preparation unless when insulin is present in excess is due to the low blood pressure.

TABLE V.—*Percentile Fall in Glycogen in Stimulated Muscle with its Blood-supply Intact.*

* St. = Stimulated till muscle would contract no longer.

Finally, something must be said concerning the behaviour of the muscle glycogen in white rats after varying degrees of exercise, either on a treadmill or by swimming in cold water. I have already alluded to the behaviour of the liver glycogen in these experiments. Table VI. shows the results for the muscles.

TABLE VI.—*Glycogen (average per cent.) in Muscles of Fasting White Rats after Exercise (with Controls). Fasting Periods 24 Hours.*

Duration of exercise.	Exercised rats.	Control rats.	No. used.	Duration of exercise.	Exercised rats.	Control rats.	No. used.

Sw. = Swimming. * Rat lost 4 g.

It is seen that even prolonged exercise in the rat does not depress the muscle glycogen very much, a result which stands out in contrast with that obtained by artificial stimulation of the muscles of a spinal preparation. With the exception of those that were made to swim in cold water off and on for 1½ hours, the rats may be said to have been in a "steady state" of activity without having been markedly exhausted at the end of it. Nevertheless, running on a treadmill for several hours is strenuous enough work for a rat. The results show that in the steady state of muscular activity, not only are the oxygen requirements of the acting muscles continuously provided for but those of glycogen as well. Glucose derived from the glycogen of the liver no doubt furnishes the raw material for the reconstruction of much of this glycogen in the muscles, but it is possible that some is also manufactured in the muscles themselves out of protein and fat. I can see no way for putting this possibility to the test of experiment, but it is significant that the percentage of blood-sugar, even after the longest periods of exercise, was practically the same in the exercised rats as in the controls. It was certainly not lower. Taking the results of both groups of experiments together, it would appear that it is only when muscular activity is so strenuous that the oxygen-supply cannot keep pace with the demands that the glycogen is significantly lowered. This would presumably be the case in muscles of the spinal cat when they are artificially stimulated and also in those of intact animals injected with strychnine or with large doses of insulin. In seven rabbits given convulsive doses of strychnine, Hershey and Orr found that the muscle glycogen averaged 0·001 per cent., the lowest value obtained after convulsions had lasted for 57 minutes being 0·03 per cent. It is worthy of note that some glycogen was always found present.

RADIUM TREATMENT BY THE IMPLANTATION OF SCREENED SEEDS.

BY JOSEPH MUIR, M.D.,
NEW YORK CITY.

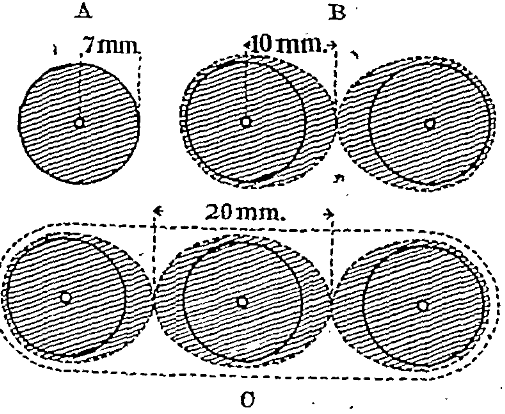
IT is now some two years since radium treatment by the method of implanting screened seeds containing radon was introduced into England. The rapidity with which this technique has made a place for itself among the longer established method of applying radium is attested by the number of papers in this and other journals in which cases so treated are described in considerable detail. In the Medical Research Council's report on the work done in certain hospitals during the year 1927 we find but one reference to the implantation of platinum radon seeds, but in Gask's Hunterian Lecture, delivered in January of last year, the method is described at length, as it is also in earlier publications of this speaker and a number of others, notably Gosse and Chester-Williams, and Stanford Cade. The general plan of treatment and its results in a rather limited field are thus fairly familiar to readers of THE LANCET. It has, however, a far wider range of usefulness, and it has seemed possible that some suggestions along this line from its originator might be of general interest to the British medical profession.

Advantages of the Screened Seed.

The advantage of the implantation method as compared with surface applications are too well known to need any amplification here. Those which the seed screened with platinum possesses over the unscreened or "bare tube" and the gold container of radon are perhaps less generally comprehended. The bare tube offers no obstacle to the passage of caustic beta radiation. Therefore a zone of necrosis invariably forms about each implanted seed. By using very minute quantities of radon in each seed the amount of this necrosis can be greatly reduced, but it can never be entirely eliminated. Moreover, when the amount of beta radiation is limited, an equal limitation is placed upon the therapeutic gamma radiation available from the same source, so that effective dosage is proportionately reduced. To offset this, a great number of these small containers must be used in a given neoplasm in order to ensure adequate dosage.

The gold seed as produced in the United States for the past three years substitutes gold for glass, the radon being gathered and placed in a long capillary tube of either material, this long tube being thereafter subdivided into seed lengths. The glass seeds are sealed off with a flame; the gold seeds are pinched with an ordinary pair of pliers, the cutting edges of which have been purposely dulled. Though this usually makes a gas-tight seal, if there are any imperfections in the gold tubing leakage is likely. The violent reactions which have been reported in some cases where the gold seed has been used were probably due to this cause. The gold seeds are estimated by their designer as being twice the size of the bare tubes, but by virtue of their wall thickness of 0·3 mm. filtering out all but 8·8 per cent. of the beta radiation. As they contain twice the amount of radon that is used in glass seeds they are capable of transmitting twice the amount of gamma radiation possible by the older method. The greatest drawback they possess—aside from the dangers of leakage already mentioned—is the "chisel-like" ends left on each seed by the method of separation with pliers. Not only are these sharp ends likely to induce unnecessary trauma as they are introduced, as there is *no* way in which they can be recovered, they must remain as an irritative foreign body in the tissues they were used to treat, a circumstance which makes it quite impossible to use them under many conditions.

FIG. 1.



The diagram (A) shows a cross-section of a platinum radon seed embedded in tissue, the cross-hatching representing the "zone of potential tissue change" about the seed: this zone is represented by a circle with a radius of 7 mm.

The diagram (B) illustrates the implantation of two seeds; cross-firing increases the zone of potential tissue change, so that the "limiting isodose line" must now be represented by the dotted line at the *periphery of the cross-hatched area*. The seeds are implanted 2 cm. apart to avoid overlapping of the zones of *potential tissue change*.

At the bottom (C) are three seeds implanted 2 cm. distant from one another. The zone of potential tissue change about each seed is represented by a cross-hatched area, showing how the effect of the centre seed is now increased by 3 mm. on each side. In actual practice it has been found that the radiation extends somewhat beyond the limiting isodose line represented by the dotted line enclosing *all three* schematic representations of the seeds and their surrounding zones of potential tissue change.

The fact that the platinum radon seed consists of a perfectly tight glass tube encased in platinum 0·3 mm. or 0·4 mm. thick, does make it, as was recently stressed by Duffy, somewhat larger than the gold seed. This disadvantage is, however, so trifling as in itself to be negligible, and when it is offset by the absolute certainty that leakage will not occur; that no trauma can be induced by its perfectly rounded ends; and that it can be removed as soon as treatment is concluded, its pre-eminence is readily recognised. Should any occasion arise wherein it is deemed undesirable to remove the seeds, the thread attached to each one can be easily omitted, though in practice this is seldom necessary. Even without its thread the platinum-screened seed is superior to the gold because of insurance against leakage and absence of irritation from the rough ends.

Application of the Platinum Radon Seed to Malignancies of the Mouth and Throat.

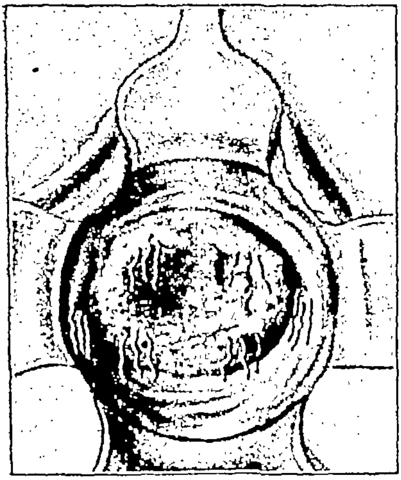
As most of the publications in England have referred only to the use of the platinum seed in treating intra-oral lesions it will be of greater interest to discuss at length some other applications of this form of therapy. Therefore it will be necessary only to touch briefly upon its use in the mouth and throat. In a publication made three years ago in the *Annals of Surgery* I called attention to the peculiar adaptability of the removable platinum seed to malignant lesions of the tongue. Especially is this true when the lesion is situated far back upon the dorsum of the tongue, where needles cannot be kept in place and no foreign body should be permitted to remain indefinitely in the tissues because of the extreme mobility of the parts. In any area of the mouth elimination of necrosis is essential because of the great vascularity of the tissues, so the assurance that no leakage of radon from the tube can occur is most desirable. Lesions at the root of the tongue and on the floor of the mouth, as well as those found in the tonsil or larynx, can be successfully implanted from the outside, thus doing away with any possibility of infection of the attached threads by the mouth secretions. This is, in practice, a purely hypothetical objection, but as it can reasonably be brought forward, it is desirable to provide against any such possibility.

In the œsophagus the dangers from tissue necrosis are perhaps greater than in any other area wherein radium therapy has been tried. Sloughing there means a fistula into lung or trachea, with rapidly fatal results. There is no doubt that a number of patients have met inevitable death sooner because of radium having been used by a method where necrosis could occur. By using the platinum-screened seed this danger is definitely eliminated, and even in cases where complete stricture had already taken place the lumen of the œsophagus has been restored to patency, and the patient so far relieved that he could return to a gainful employment, resuming his ordinary diet and habits.

Implantation as an Adjunct in Gynæcology and Urology.

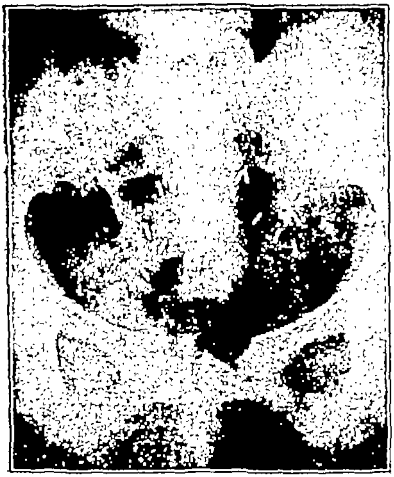
The treatment of early and moderately advanced cancer of the uterine cervix by radium has now been so standardised as to rank with surgery as an efficient method of treatment, being regarded as the method of choice in many clinics. In such a cavity as the uterus, however, the implantation method has, apparently, no place. Yet during the past three years this particular form of radium therapy has found an ever-increasing usefulness in cases showing involvement of broad ligaments and vagina, in which all methods—of surgery and radium alike—have heretofore proved impotent. When the cervical canal is completely blocked by malignant exuberations, or the cervix has become a sloughing mass, insertion of the usual uterine applicators becomes impossible. The woman who presented such a condition was once doomed to die unaided by anything more than palliation. Yet it is now possible for a skilful operator

FIG. 2.



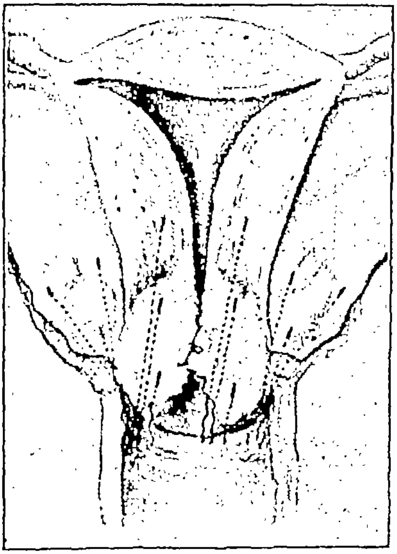
Advanced carcinoma of the uterine cervix. Removable platinum seeds have been implanted in the infiltrated tissues of the malignant cervix.

FIG. 4.



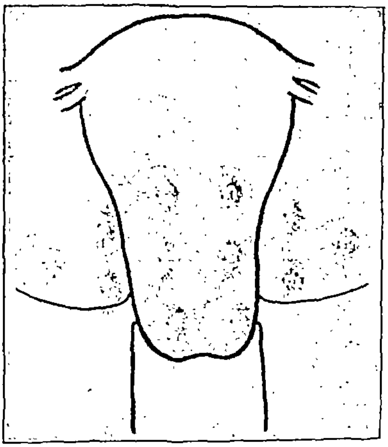
Advanced carcinoma of the uterine cervix. Radiogram showing platinum seeds in position, immediately after implantation.

FIG. 3.



Advanced carcinoma of the uterine cervix. Cross-section (semi-schematic) showing the position of the implanted seeds in relation to the seed-threads.

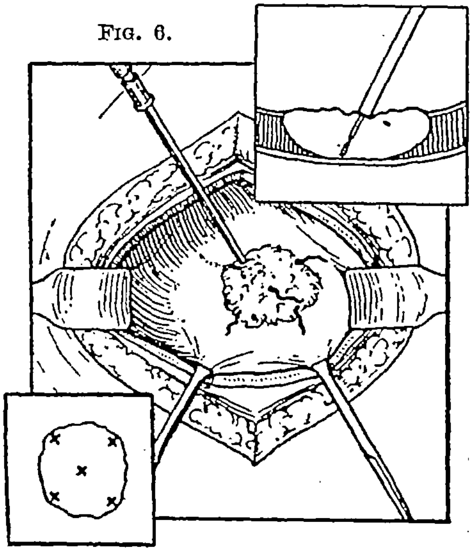
FIG. 5.



Advanced carcinoma of the uterine cervix. Schematic view showing zones of tissue irradiated by each seed.

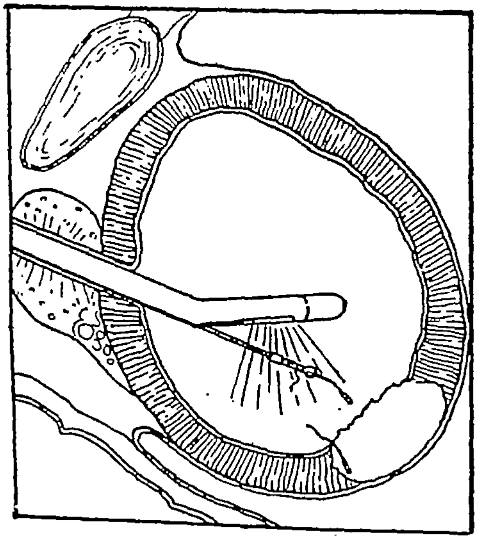
to implant even the highly friable tissues infiltrated by advanced carcinoma, and to remove the seeds after a suitable exposure, without inflicting any further trauma upon the carcinomatous area. The effect of such treatment has proved astonishing. The intolerable pain rapidly subsides, foul-smelling discharge is lessened or ceases altogether, elimination of the toxic focus polluting the blood stream permits a marked improvement in the patient's general condition. The malignant area "cleans up" in a short time to such an extent that it will be possible to make use of the regular means of applying radium, as is done in the cases seen when only moderately advanced. So much benefit has accrued to this hitherto hopeless class of patients that even if we regard it merely as a form of palliation, the results amply justify the employment of the method.

FIG. 6.



Carcinoma of the bladder. Implantation of removable platinum radon seeds through suprapubic cystotomy. Note distribution of seeds as shown by protruding threads. Insert shows relative position of seeds (at left); actual deposition of seed at base of tumour (at right). The shoulder of the implanter limits the depth of implantation to 1 cm.

FIG. 7.

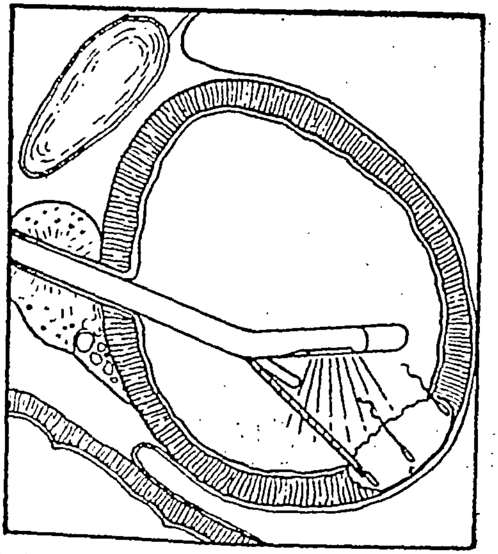


Implantation of removable platinum seeds through the cystoscope using flexible cystoscopic implanter. Protruding threads serve as a guide to the operator in the proper distribution of the seeds.

In lesions lower down in the general tract, carcinoma of the vagina and vulva, implantation may be employed by the same general technique which has been indicated for similar types of lesion elsewhere. Cancer of the vulva is very seldom seen, but in those few cases where the method has been used the results have been eminently satisfactory.

It is in dealing with vesical neoplasms in both sexes that the implantation of screened seeds has found one of its greatest fields of usefulness. The bare tubes formerly used showed, despite the serious objection of necrosis production, that radium was a very effective agent in combating malignancy in the bladder. When the dangers of necrosis and sloughing were eliminated by the introduction of proper screens, the popularity of radium as a substitute for surgery or fulguration rapidly increased. In the recently issued text-book of Eisendrath and Rolnick the method of implantation is dwelt upon at considerable length. When removable platinum radon seeds are used the operation may be carried out either cystoscopically or through a suprapubic incision, but its usefulness in connexion with cystoscopic work especially commends it.

FIG. 8.

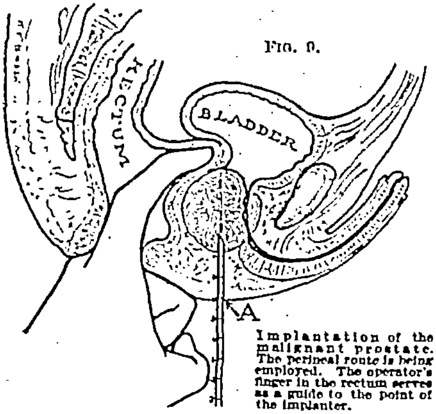


Illustrating method of removing seeds through the cystoscope after adequate dosage has been delivered. This may be done with the ordinary cystoscopic forceps.

"One employs a seed filtered by 0·8 mm. of platinum, capable of delivering a dosage of 333-1/3 millicurie hours—that is, 2·5 millicuries of radium emanation destroyed in ten day's time. These seeds are placed in the neoplasm at a distance of 2 cm. apart. The Muir implanter is passed through the channel of an operating cystoscope. The site for the deposit of the first seed having been selected, the point of the implanter is thrust into the neoplasm and the seed placed in the loading slot. This seed, pushed by the plunger, is carried into the tissues to a predetermined depth. When it reaches this depth, its progress is automatically halted by the shoulder of the instrument which prevents the point from advancing beyond a certain distance. When the instrument is withdrawn, the seed remains in place, the thread attached to it being plainly visible protruding from the point of entrance. The first seed deposited thus serves as a landmark, from which the proper location of all subsequently to be implanted can be readily ascertained. The total number, of course, depends upon the size of the growth and the estimated invasion of the surrounding bladder wall by possible malignancy. . . . When the period of exposure to radiation has expired—this is ordinarily nine or ten days—the seeds are withdrawn through the cystoscope, using either an ordinary forceps or an instrument specially designed to meet this need. The threads attached to the seeds must be cut off to a length not exceeding one centimetre before being placed in the loading slot, for if too long they may become entangled in the cystoscope as that instrument is withdrawn, and the seeds thus displaced or even dislodged entirely. With the exercise of a little care and deliberation, however, such accidents can be readily avoided."

In treating malignancy of the prostate it is customary to permit the seeds to remain permanently in the tissues, which causes no foreign body reaction nor irritation when the smoothly rounded platinum seeds are used. The implantation is generally done under novocaine infiltration; occasionally, when indicated, the sacral method is used successfully. Implantation is done preferably through the perineum, but where a suprapubic opening already exists it may be utilised for open insertion. A few operators make a suprapubic exposure especially to facilitate the implantation. The operator keeps his left index-finger in the rectum to guide the needle point of the implanter; when he feels the resistance of the tissues to the advance of the needle he will realise that the point has penetrated to depth sufficient to permit the seed to be deposited. The deepest seed must be deposited first, otherwise implantation may begin on either side. Four seeds are customarily employed, being deposited at the apices of the prostatic lobes in such a way as to bear the relation one to another such as is borne by the apices of a right-angle pyramid. But one portal of entry is necessary. The angle of the handle of the implanter can be altered without entirely withdrawing the instrument. The point can be withdrawn and the angle changed so that each seed will be deposited not less than 2 cm. from the others. The arrangement of the seeds can be clearly seen in the accompanying diagram (Fig. 10).

FIG. 9.

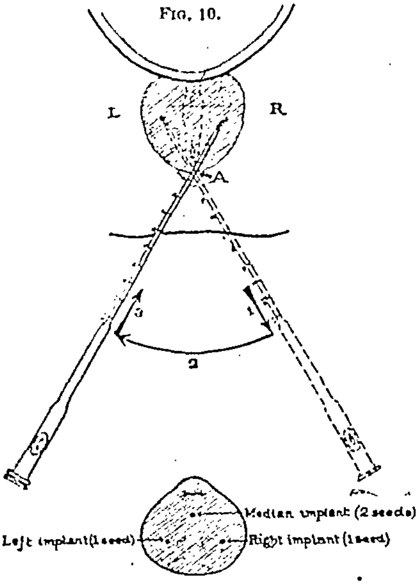


Implantation of the malignant prostate. The perineal route is being employed. The operator's finger in the rectum serves as a guide to the point of the implanter.

Suprapubic insertion does not differ especially from the transperineal technique, though the work is naturally much simplified by the free exposure of the site of malignancy. The seeds generally used in either case contain 2·5 millicuries of radon, which when left permanently in situ provides 333-1/3 millicurie hours of gamma radiation. This method of treating malignancy of the prostate will be found vastly superior to needles which have proved so traumatising that they have been largely abandoned in American clinics where much prostatic work is carried on. Lowsley and Kirwin in their text-book call attention to the possibility of permitting these prostatic patients to leave the hospital much sooner than under any other conditions of treatment. "This possibility of escaping the prolonged hospital stay will often induce him to undertake the radium treatment when other forms of therapy would be refused."

The simplicity and accuracy which are among the *most salient features of this technique have greatly* extended the field of usefulness within the bounds of which radium has in the past been so closely restricted. It should serve to bring about rapid fulfilment of the prophesy made a few months ago by Mr. Hayward Pinch that, "in the very near future radium would form as much a part of the up-to-date surgeon's armamentarium as the scalpel," and it might be added—will prove itself as generally useful.

FIG. 10.



Implantation of the malignant prostate. The method of altering the angle of the implanter, so as to place the seeds at the different angles desired, is here shown. Insert gives schematic representation of the prostate after implantation is completed.

THE CHOLESTEROL OF THE BLOOD PLASMA IN EPILEPSY.

By MINNIE GOSDEN, M.B. Lond.,
LATE ASSISTANT MEDICAL OFFICER, LINGFIELD EPILEPTIC COLONY;
J. TYLOR FOX, M.D. Camb., D.P.M.,
MEDICAL SUPERINTENDENT OF THE COLONY;
AND
W. RUSSELL BRAIN, D.M. Oxf., M.R.C.P. Lond.,
ASSISTANT PHYSICIAN TO THE LONDON HOSPITAL AND TO THE HOSPITAL FOR EPILEPSY AND PARALYSIS, MAIDA VALE.

THERE have been many attempts to find some chemical change in the blood related to epileptic seizures, though until recently they have met with but little success. Lately, however, several observers have reported alterations in the blood cholesterol in epileptics. De Crinis[3] in 1920 stated that the blood cholesterol was increased before an attack. Pezzali[6] in 1923 found uniformly low levels of the blood cholesterol in epileptics, especially during seizures. Popéa and Vicol,[7] noting that the lipoid was almost absent from the suprarenals after death in status epilepticus, found a decrease in the blood cholesterol during and after the attacks. They concluded that the fall was due to the consumption of the circulating cholesterol during the fits. Robinson, Brain, and Kay[8] found that the average blood cholesterol level in a group of epileptics was lower than in a corresponding group of controls, and that the average level was lower in blood taken within 24 hours of a fit than in blood taken after a longer interval. They found that the fall in the blood cholesterol preceded the attack in 10 out of 11 cases in which serial estimations were made. Osnato and Killian,[5] and Goodall[4] have also investigated the blood cholesterol in epilepsy but with negative results. Their deductions, however, are open to criticism and we shall discuss them later.

The present paper is an account of serial estimations of the cholesterol content of the blood plasma in 21 epileptics and five controls, comprising two normals and three patients suffering from diseases of the nervous system other than epilepsy.

Method.

The method employed was that of Bloor,[1] the only modification being that 1 c.cm. of plasma was used in 25 c.cm. of the alcohol and ether mixture. It has been found that this method will only give satisfactory results if the instructions in the original paper are strictly adhered to. In this series of estimations there has been little difficulty in matching the green colour produced, but it has been found that the following conditions are important. All glassware used in the final extraction with chloroform must be absolutely freed from moisture, preferably by drying in hot air; if this is not done a yellow tinge in the final green colour makes it difficult to match with the standard, and also gives too low a result. The acid used to develop the colour must be fresh and the amount (0·1 c.cm.) very accurately measured; the slightest excess gives a blue tinge in the green. The colour develops best within Bloor's limits of temperature—viz., 20–22°C.—and readings should be made 12 to 15 minutes later. It has been noticed that the colour does not develop fully in less than ten minutes and may begin to fade if left much over 15 minutes; consequently not more than six or seven estimations can be made with the same standard. With every precaution we have found that the method gives a difference of about 3 per cent. in different estimations of the same samples of plasma—e.g., in three separate such estimations on the same sample the results were as follows:—

1. 0·203 }
2. 0·202 } Per cent. of cholesterol
3. 0·208 } in 100 c.cm. plasma.

Therefore in the following series variations of less than 10 mg. between successive estimations may be due to experimental error. The estimations have been done on oxalated blood plasma, obtained by venepuncture. Estimations on whole blood have not been included, as experience showed that after extracting this with the boiling alcohol and ether mixture the extract had, in some cases, a brownish tinge which interfered with the final colour. This did not occur with blood plasma.

It will be appreciated that the necessity for repeated venepunctures made it difficult to secure a large series of estimations, especially in children. Moreover, venepuncture was usually impossible when status epilepticus was actually in progress. Most of the observations have been made during the night with the patients at rest in bed, several hours after the last meal. This has been done partly because the fit incidence is higher at night and partly to eliminate the effect of meals and of possible changes due to muscular exercise, although, as a matter of fact, in curves obtained during the day meals alone did not affect the level (see Series 12 and 13 in Appendix I.). The epileptics investigated were all patients living an active outdoor life at the Colony, Lingfield, and were clinically healthy except for fits; patients with conditions known to be associated with a low blood cholesterol—e.g., anæmia or infective conditions—were not included, and all the cases, with two exceptions (Nos. 12 and 29), apparently belong to the "idiopathic" group.

We regret that owing to one of us leaving England, it was not possible for us to include as many determinations of the plasma cholesterol in controls as we should have liked. We felt that it was better to publish our investigations as they stood, rather than that the determinations in normals and epileptics should be made by different persons. The lack of controls, of course, does not affect the validity of conclusions based upon differences in the plasma cholesterol in different groups of epileptics, and the normal blood cholesterol as determined by the method we employed is well established.

Average Plasma Cholesterol Level in Epileptics.

The first point to which we shall direct our attention is whether or not our investigation confirms the findings of Robinson, Brain, and Kay that the average blood cholesterol level is lower in epileptics than in normals, and lower at a time near the convulsion than in intervals of freedom from attacks.

The normal level of blood cholesterol varies within fairly well-defined limits. Campbell[2] gives the normal figures for free and ester cholesterol as from 0·150 to 0·230 per cent. Robinson et al, using Sackett's[9] modification of Bloor's method, gives the following values for plasma:—

	Max.	Min.	Mean.
39 males	0·212	.. 0·142	.. 0·163
32 females	0·217	.. 0·133	.. 0·172

Sackett obtained results varying from 0·115 to 0·280.

As our investigation was not primarily directed to determine average levels we have not performed a number of determinations upon normals. Two healthy persons, however, upon whom serial determinations were made yielded means of 0·241 and 0·207 per cent.; and we have also employed as controls three patients suffering from diseases of the nervous system other than epilepsy.

The following table embodies our results so far as they throw light upon the average plasma cholesterol level in epilepsy:—

Present investigation.					Robinson, Brain, and Kay.
Class of patient.	Patients.	Series.	Readings.	Average (plasma cholesterol).	
Controls	5	5	32	187	167
Epileptics: Blood removed more than 24 hours before or after a fit	7	10	59	142	155
Epileptics: Blood removed within 24 hours of a fit, excluding cases of status ..	15	17	111	137	135
Epileptics: In status or serial epilepsy	4	5	26	100	—

These figures appear to us to justify two conclusions:—

1. The average blood cholesterol in this group of 10 epileptics is below normal.

2. Status epilepticus and serial epilepsy are associated with especially marked depression of the blood cholesterol. The extremely low figure of 0·030 per cent. was obtained in one of our patients at the end of a severe attack of status. The numbers are insufficient to justify any conclusion being drawn as to the relative level of the blood cholesterol at times near and remote from the attack.

Osnato and Killian [3] have criticised the findings of Robinson, Brain, and Kay and drawn contrary conclusions on grounds which appear to us entirely inadequate. They report a single determination of the blood cholesterol in 22 epileptics, in four of whom the blood was obtained within 24 hours of a fit. Such small numbers in our opinion justify no conclusion whatever as to the behaviour of the blood cholesterol in relation to the fits. Osnato and Killian criticise Robinson, Brain, and Kay on the ground that the blood cholesterol varies in normals during the day more than the difference between normals and epileptics. Such criticism is misdirected, and appears to be based upon a misunderstanding of the nature of averages. In the series of Robinson, Brain, and Kay there are 121 epileptics and 71 controls. Any normal variation ought on Osnato's hypothesis to be common to both groups and cancel out. It is unthinkable that, as he seems to imply, 121 epileptics should all have been examined by chance at the lower part of their normal range, and the controls all by chance at the upper part. The same fallacy underlies Osnato's stress upon anæmia or fever as possible causes of the differences between normals and epileptics, since the controls were taken from the same hospital population as the epileptics. Osnato and Killian, moreover, performed no serial blood cholesterol determinations in epileptics, and misquote the number performed by Robinson, Brain, and Kay as 2 instead of 11.

Goodall [4] has recently published the results of an investigation of the blood cholesterol level in six epileptics, three determinations being made in the interparoxysmal and three in the preparoxysmal period. He states that "the mean value for the blood cholesterol in the preparoxysmal phases is not markedly different from that in the interparoxysmal phases. The variations from the mean tend to be greater in the former," and "the preparoxysmal cholesterol usually tends to be slightly lower than the interparoxysmal value." Goodall's findings, as far as they go, appear to support the conclusions of Robinson, Brain, and Kay, but we feel that it would not be justifiable to lay much stress upon them. Since the blood cholesterol in epilepsy may vary greatly from hour to hour especially in the proximity of a fit, it is doubtful if much information can be gained from so small a number of determinations. Either the serial method or the averaging of determinations in large groups would seem to be essential.

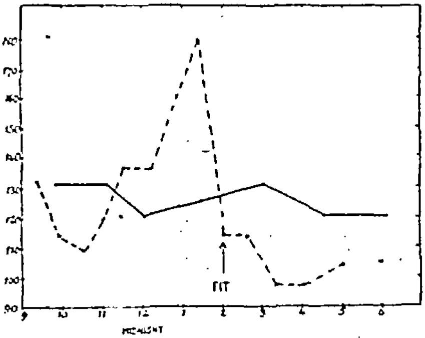
Variability of Cholesterol Level in Epileptics.

Our special object in this investigation was to study the behaviour of the plasma cholesterol level in epileptics by means of serial determinations, to observe whether abnormal variations in the level occurred, and, if so, whether these were in any way related to the occurrence of fits.

It is first necessary to form an opinion as to the normal limits of variation of the blood cholesterol. The simplest mode of expressing the variability as determined over a given series of determinations is to take the average level of the series and the range—i.e., the difference between the highest and lowest value in the series—and to express the range as a percentage of the average. For example, if the average of seven serial determinations were 150 mg. per 100 c.cm., the highest value obtained being 200 and the lowest 125, then the range is 75, and $\frac{\text{range}}{\text{average}} = \frac{75}{150} = 50$ per cent.

There are comparatively few data upon which to base an opinion as to the normal variability of the blood cholesterol. We have made two series of determinations on healthy adults, yielding variabilities of 5 per cent. in each case; and three series of determinations on patients suffering from organic disease of the nervous system not associated with convulsions—namely, two early cases of disseminated sclerosis and one case of parkinsonism following epidemic encephalitis. These patients, who, of course, cannot be treated as normals, yielded variabilities of 13, 22, and 5 per cent. Osnato and Killian quote Somach and Halpern who made four serial determinations on four normals. The variability in these normals estimated by us from the published charts was approximately 15, 12, 27, and 10 per cent. The average variability of these nine series of determinations on non-epileptics, six of whom were normals, was about 13·3 per cent.

We have divided the serial determinations we have made upon epileptics into two groups: (1) those which do not include a fit, and (2) those in which a fit occurred during the period in which determinations were made. The average variability in the former group was 20 per cent., and in the latter 31 per cent. Thus the occurrence of a fit during the period of observation is found to be associated with a variability of the blood cholesterol level which is 50 per cent. greater than when no fit occurs, in which case the variability differs little from the normal.



Charts representing two series of determinations of the plasma cholesterol of the same patient made on dates separated by two months. The continuous line represents the series in which no fit occurred, the interrupted line a series including a fit, which began as the blood was withdrawn at 2 A.M. The marked fall in the plasma cholesterol between 1.15 and 2 A.M. thus preceded the attack. (Series Nos. 8 and 21.)

Consideration of Some Individual Series.

Certain points of interest emerge from a consideration of individual series of determinations.

(1) *Cholesterol Instability Without a Fit.*—Three series of determinations, Nos. 15, 16, and 17, showed abnormal variability—namely, 57, 42, and 35 per cent. respectively, without a fit occurring. Series 15 and 16 were made on the same patient, and in each case because it was thought likely that a fit would occur as the patient exhibited the usual prodromal manifestations. This expectation, however, was not fulfilled, yet the cholesterol instability often associated with a fit occurred.

(2) *Fall in Blood Cholesterol Level Preceding a Fit.*—Robinson, Brain, and Kay made 11 series of determinations preceding an attack and found that in ten of these a fall in the blood and plasma cholesterol

preceded the attack. We have records of 12 series which include attacks, but only four of these are comparable with Robinson, Brain, and Kay's series in that a number of determinations were made before an attack. In three of these four the attack was, as in Robinson's series, preceded by a fall in the plasma cholesterol. The accompanying chart is of interest as illustrating two series of determinations made in the same patient, one including and one (No. 8) not including an attack. It will be observed that the curve which includes an attack exhibits the pre-paroxysmal fall described by Robinson, Brain, and Kay, previous to which the cholesterol level is high as De Crinis observed. The marked variations occurring in the space of a few hours show how misleading a single determination of the blood cholesterol may be. Determinations separated by only three-quarters of an hour—namely, those at 1.15 A.M. and 2 A.M. differ by 64 mg. per cent. An isolated determination would lead to diametrically opposite conclusions concerning the blood cholesterol level according to whether it was made at the former or the latter time, both of which are within an hour of an attack. It is in the light of such observations that we feel bound to criticise the adequacy of the data upon which Osnato and Killian and Goodall base their conclusions.

Conclusions.

The task of conducting biochemical investigations into epileptics is beset with difficulties, of which the chief is to obtain material immediately before a convulsion. Our attempts to achieve serial estimations of the blood cholesterol before a fit were successful on only four occasions. But we have in addition obtained serial estimations in a number of cases of status epilepticus and serial epilepsy.

Our figures confirm the observation of Robinson, Brain, and Kay that the average blood cholesterol level in epileptics is subnormal, and that of Popéa and Vicol that it is exceptionally low in status epilepticus and in serial epilepsy. We have also found that the blood cholesterol level is more variable in epileptics at about the time of a fit than in periods of freedom from attacks; and that in three out of four cases a fall in the cholesterol level preceded an attack, as Robinson, Brain, and Kay first observed. In our present state of ignorance concerning both the nature of a convulsion and the metabolism of cholesterol we can offer no opinion as to the nature of the association between changes in the blood cholesterol level and the occurrence of fits.

APPENDIX I.

Serial Determinations of the Plasma Cholesterol in Non-epileptics.

1. Normal, male, aged 44. Night of Jan. 28th–29th.

10 P.M.	0·238	2.30 A.M.	0·242
11.30 P.M.	0·238	4 A.M.	0·247
1 A.M.	0·235	5.35 A.M.	0·247

2. Normal, female, aged 34. Night of Jan. 28th–29th.

10.30 P.M.	0·208	2.45 A.M.	0·202
11.45 P.M.	0·202	4.10 A.M.	0·213
1.15 A.M.	0·208	6 A.M.	0·210

3. Early disseminated sclerosis. Male, aged 22. Night of Dec. 21st–22nd.

9.5 P.M.	0·178	3 A.M.	0·166
10.35 P.M.	0·178	4.30 A.M.	0·172
12.5 A.M.	0·156	6 A.M.	0·170
1.35 A.M.	0·166		

4. Early disseminated sclerosis. Male, aged 22½. Night Dec. 21st–22nd.

9 P.M.	0·179	3 A.M.	0·185
10.30 P.M.	0·185	4.30 A.M.	0·208
12	0·179	6 A.M.	0·208
1.30 A.M.	0·166		

5. Post-encephalitic parkinsonism. Male, aged 21. Night of Dec. 21st–22nd.

9 P.M.	0·125	3 A.M., specimen broken.	
10.30 P.M.	0·129	4.30 A.M.	0·128
12	0·125	6 A.M.	0·130
1.30 A.M.	0·124		

Serial Determinations of the Plasma Cholesterol in Epileptics.

Group 1. Series not including an attack.—Nos. 6 and 7 (G. H.). Two serial estimations, first during the morning of July 9th, and next during the night of Nov. 5th–6th. Last fit in No. 6 on July 6th, next on July 11th. Last fit in No. 7 on Oct. 30th, next on Nov. 6th. Drugs (routine): bromide grs. 10 in morning and grs. 20 with grs. 2 of luminal at night.

No. 6.	July 9th.	No. 7.	Nov. 5th–6th.
11.30 A.M.	0·119	10 P.M.	0·125
12.30 P.M.	0·119	11 P.M.	0·131
2.30 P.M.	0·119	12	0·119
		1 A.M.	0·125
		4 A.M.	0·122
		5.30 A.M.	0·119

No. 8 (A. C.). During night of Sept. 14th–15th. Last fit Sept. 12th, next on Sept. 17th. Drugs (routine): bromide grs. 20 at night. (See also No. 21.)

10 P.M.	0·131	3 A.M.	0·131
11 P.M.	0·131	4.30 A.M.	0·119
12	*0·119*	6 A.M.	0·110
1.30 A.M.	0·125		

No. 9 (A. E. B.). Night of Nov. 5th–6th. Last fit Oct. 23rd, next on Nov. 14th. Drugs: bromide grs. 20 and luminal grs. 2, at night.

10 P.M.	0·179	2.30 A.M.	0·183
11 P.M.	0·179	4 A.M., specimen lost.	
12	0·186	5.30 A.M.	0·179
1 A.M.	0·179	(See also Nos. 14, 15, 16.)	

No. 10 (H. B.). Night of July 21st–22nd. No fit for a year. Four grains of luminal were given during the night as an experiment, but it had no apparent effect on the cholesterol level.

10 P.M.	0·108	3 A.M.	0·108
12	0·104	4 A.M.	0·101
2 A.M.	0·108	6 A.M.	0·108

No. 11 (A. G. M.). Night of Nov. 5th–6th. Last fit early morning of Nov. 5th, next on Nov. 24th. No. 32 is from the same patient during a night when a fit occurred. Drugs (routine): nil.

10 P.M.	0·125	2.30 A.M.	0·133
11 P.M.	0·125	4 A.M.	0·109
12	0·125	5.30 A.M.	0·125
1 A.M.	0·130		

No. 12 (S. C.). During day of Nov. 20th. Last fit three days previously, next fit five days later. Drugs: luminal grs. 2 at night.

11.15 A.M.	0·102	3.5 P.M.	0·104
12.5 P.M.	0·099	4.35 P.M.	0·106
1.35 P.M., specimen lost.		6.5 P.M.	0·108

No. 13 (P. E. W.). During day of Nov. 20th, 1928. Major fit a few hours previously; next fit seven days later.

11.10 A.M.	0·093	4.30 P.M.	0·089
1.30 P.M.	0·075	6 P.M.	0·090
3 P.M.	0·088		

No. 14 (A. E. B.). (See also No. 9.) During morning of July 21st. He got up saying he felt he was going to have a fit, but was determined to stop it as he wished to play cricket that afternoon. No fit occurred.

8.30 A.M.	0·204	10.20 A.M.	0·192
9.15 A.M.	0·192	12 noon	0·179

No. 15 (A. E. B.). During night of July 21st–22nd. The sister in charge of the home was confident that a fit would occur during this night, as the patient had been irritable and a fit was due. Last fit June 20th; next August 1st. No fit occurred in July, the average number for other months being three.

8.45 P.M.	0·217	12.15 A.M.	0·156
10 P.M.	0·156	1.45 A.M.	0·168
10.45 P.M.	0·142	3 A.M.	0·105
11.15 P.M.	0·125	6.30 A.M.	0·174

No. 16 (A. E. B.). During night of Sept. 14th–15th. A fit was similarly predicted but did not occur. Last fit August 23rd; next Sept. 20th.

10.5 P.M.	0·147	3.5 A.M.	0·122
11.5 P.M.	0·099	4.35 A.M.	0·147
12.5 A.M.	0·109	6 A.M.	0·139
1.45 A.M.	0·109		

No. 17 (E. S.). During night of July 21st–22nd. This was a patient who was liable to multiple automatic attacks at night, but was then in a period of freedom from attacks. No. 25 is from the same patient when attacks occurred. Drugs: luminal grs. 4 at night.

10.15 P.M.	0·101	3.45 A.M.	0·128
11.15 P.M.	0·174	4.45 A.M.	0·156
12.15 A.M.	0·184	6 A.M.	0·130
1.45 A.M.	0·174		

No. 18 (H. D.). During night of Sept. 14th-15th. Last fit four years previously. Drugs: luminal grs. 2 at night.

10 P.M.	0·128	3 A.M.	0·113
11 P.M.	0·125	4.30 A.M.	0·147
12	0·119	6 A.M.	0·140
1.30 A.M.	0·147		

No. 19 (C. J. H.). During night of Sept. 14th-15th. The attendant at the home felt sure this man would have a fit during the night. The fit occurred at 11 A.M., five hours after the last cholesterol determination. This patient is very rarely convulsed during the day.

10 P.M.	0·128	3 A.M.	0·113
11 P.M.	0·125	4.30 A.M.	0·147
12	0·119	6 A.M.	0·140
1.30 A.M.	0·147		

No. 20. (O. O.). During day of Nov. 20th. Last fit five hours previously. A major fit is usually followed by another in a few hours, but this did not occur on this occasion. Drugs: luminal gr. 1 in morning; bromide gr. 10 at night.

11.5 A.M.	0·119	3.15 P.M.	0·147
12 noon	0·138	4.40 P.M.	0·132
1.40 P.M.	0·114	6.15 P.M.	0·114

Group 2. Series in which fits occurred during observation.—It has not been found easy to collect specimens showing estimations just before fits as their occurrence is so irregular, and so few patients have any but a brief warning. The results which have been obtained are as follows:—

No. 21 (A. C.). During night of July 14th-15th. A major fit occurred at 2 A.M. Fits occurred on nine previous nights and on the following night. No. 8 is a curve from the same patient during a night without a fit.

9.35 P.M.	0·132	1.15 A.M.	0·178
10.5 P.M.	0·114	2 A.M.	0·114*
10.35 P.M.	0·109	2.30 A.M.	0·114
11.5 P.M.	0·119	3.15 A.M.	0·099
11.35 P.M.	0·136	4 A.M.	0·096
12.5 A.M.	0·136	5 A.M.	0·104

*Major fit commenced as this specimen was being collected.

No. 22 (W. H. T.). Night of July 18th-19th, with two major fits at 5.45 A.M. and 7.45 A.M. Previous fit on June 17th. Several fits followed during the two days after the cholesterol determination.

9.30 P.M.	0·132	3.30 A.M.	0·141
10.15 P.M.	0·132	5 A.M.	0·137
11.45 P.M.	0·119	6 A.M.	0·120
1.30 A.M.	0·125	6.30 A.M.	0·120
2.30 A.M.	0·132	8 A.M.	0·150

No. 23 (W. W.). During day, Nov. 21st. Major fit at 10.50 A.M.

10.15 A.M.	0·100	11.15 A.M.	0·094
10.45 A.M.	*0·087*	*11.45 A.M.*	0·110

No. 24 (M. C.). During day, Dec. 14th. A few estimations during a long period of serial epilepsy. Fits at 9.35, 11.20, and 11.55 A.M., and 12.27 P.M.

9.30 A.M.	0·109	11.40 A.M.	0·109
10.10 A.M.	0·116	12.30 P.M.	0·110
10.40 A.M.	0·109	1 P.M.	0·111
11.10 A.M.	0·100		

No. 25 (E. S.). During night of Jan. 25th-26th. Attack of automatism at 0.10 A.M. (See also No. 17.)

10.45 P.M.	0·208	4.5 A.M.	0·181
11.35 P.M.	0·214	5.45 A.M.	0·181
1 A.M.	0·211	6.25 A.M.	0·178
2.35 A.M.	0·195		

No. 26 (H. R. M.). During day, July 22nd. *These estimations made during a severe attack of status epilepticus.* The attack started at 6.5 A.M. and stopped at 7.30 A.M. At 7.10 the patient stopped breathing and was in a very serious condition. Drugs (routine): bromide, grs. 30, at night; luminal, grs. 2, in morning.

7.15 A.M.	0·061	8 A.M.	0·083
7.40 A.M.	0·036	8.45 A.M.	0·093

No. 27 (H. R. M., same patient as 26). These estimations were made in another attack of status, on Sept. 11th, when his condition was not quite so serious. The status began at 5.15 A.M. Thirty major fits occurred between 5.15 and 5.36 A.M. without return of consciousness between. Then fits occurred at 5.46, 5.55, 6.10, and 6.20 A.M., when the attack ended.

APPENDIX II.

Clinical Notes on Epileptic Patients Investigated.

Nos. 6 and 7 (G. H.). Male, aged 21. Four brothers and sisters died of convulsions a few days after birth, another stillborn. Physically ill-developed and undersized, but much stronger than formerly. Mentally dull. Stricture of posterior urethra (? congenital) treated surgically in 1927. First fit aged 8. About five attacks a month with unconsciousness and partial or complete convulsions. A few automatic attacks in addition.

No. 8 (A. C.). Male, aged 25. Father committed suicide. Mother alcoholic. Father's cousin epileptic. Mentally normal and physically robust. First fit aged 13, ascribed to concussion two years earlier. Large number of major fits, almost all at night, averaging ten a month. Often has fits every night for a week or more at a time. Occasional short attacks of automatism.

No. 9 (A. E. B.). Male, aged 26. Both parents died insane. Formerly of normal intelligence, but now deteriorating mentally. Physical condition good. First fit aged 14. Very large number of major attacks chiefly in small groups.

No. 10 (H. W. B.). Male, aged 25. Severe head moulding at birth. Some asymmetry of chest. Left-handed. Mentally normal. Physically frail. First fit aged 14. Frequent major fits persisted for six years. Recurred a year later in smaller numbers. Last fit recorded Sept., 1927.

No. 11 (A. G. M.). Male, aged 22. Some stigmata. Large and coarse features. Large square hands with thick fingers. Ears, lobules adherent. Slow slurring speech. Some tremor. Poor circulation. Mentally dull and deteriorating. First fit aged 12 (? due to sunstroke). Large number of majors, often occurring in series, lasting a few days and accompanied by some mental confusion. Considerable improvement last six months apparently due to pot. borotartrate.

No. 12 (G. C.). Male, aged 16. Mentally three years retarded and deteriorating. First fit aged 6, occurred within 24 hours of a fracture of the skull. Fits recurred at the age of 10. A year later trephined in right fronto-parietal region and bone, said to be pressing on the brain, removed. No improvement in fit incidence resulted. Now has about seven major attacks a month, the left side being more involved than the right.

No. 13 (P. E. W.). Male, aged 23. Mother hysterical. Physical condition and intelligence good. Mentally rather unstable. First fit aged 3, recurred aged 8. Major attacks have occurred regularly since, with rather increasing frequency, now averaging six a month.

Nos. 14, 15, and 16: see No. 9 above.

No. 17 (E.S.). Male, aged 35. Physical and mental condition good. First fit aged 23, supposed to be due to being blown up and buried a year previously. Major fits, ten in 1927 and two in 1928. Short automatic attacks, characterised by extreme fright and screaming and almost always arising in sleep have occurred for years. The number varies from one up to six a night. The periods of freedom from these attacks are now increasing, and during 1928 he was clear for eight consecutive months. The improvement may be due to luminal, grs. 4, nightly.

No. 18 (H. D.). Male, aged 25. Mother had fits and died of tumour of the brain. Brother died of convulsions while teething. Father intemperate. Mentally a little dull. Physically strong. First fit aged 13, ascribed to a fall.

Very frequent major fits, often in series and sometimes accompanied by grave mental confusion, until in 1924 luminal medication (grs. 2 daily) was started, since when fits have been completely absent.

No. 19 (C. H.). Male, aged 33. Physical condition good. Mentally deteriorating. First fit aged 25, supposed to be due to heatstroke in India. Major fits, all at night, occur at the rate of seven or eight a month.

No. 20 (G. G.). Male, aged 17. One sister insane. Undersized. Face and head asymmetrical. Ears prominent. High palate. Hyper-extensible joints. High grade feeble-minded. First fit aged 10. Mostly major type in groups of three or four.

No. 21 (A. C.). (See No. 8 above.)

No. 22 (W. H. T.). Male, aged 22. Mentally dull and deteriorating. Physically fairly strong. First fit aged 7. Major attacks often in groups of eight or ten spread over three or four days, averaging four or five a month in all.

No. 23 (W. S. W.). Male, aged 12. Physically and mentally normal in spite of frequent fits. First fit aged 11 months, ascribed to fall on the head two months previously. Major attacks occur in groups from one to eight about once a month.

No. 24. (M. C.) Female, aged 14. Physical condition good. Mentally a little subnormal. First fit aged 12 months. Second attack a few years later. During 1928 isolated major fits every two or three weeks, gradually becoming more frequent until the beginning of December, when they averaged 20 a day and are still (1/2/29) continuing at about the same rate.

No. 25 (E. S.). (See No. 17 above.)

Nos. 26 and 27 (H. R. M.). Male, aged 26. Formerly in the Navy. Mentally deteriorating. Physical condition fair. First fit aged 7, said to have followed a fall downstairs. Large and increasing numbers of major fits. Prolonged series of true status epilepticus every few weeks. A case of severe epilepsy.

No. 28 (L. N. D. L.). Male, aged 18. Physically hypotonic. Tremors, some stigmata. Intelligence nearly normal, but conduct very abnormal, especially when fit incidence is high. First fit aged 8. Large numbers of attacks, mostly major in type, occurring very irregularly.

No. 29 (J. D.). Male, aged 28. A sister died of convulsions at 18 months. Feeble-minded and deteriorating. Physically not robust. Slight right hemiplegia. First fit aged 2. Now has about three isolated majors a month, and, in addition, about two attacks of status epilepticus, lasting 15 to 60 minutes, a year.

No. 30 (V. T.). Male, aged 16. Father had convulsions during teething, and mother's mother died of asthma. Mentally and physically normal. First fit aged 7, ascribed to measles. Major attacks average two a month. Also very large numbers of slight attacks consisting of jerking head and eyes to right, and lasting two or three seconds. (These were diagnosed at one time as a sternomastoid tic.) Luminal partly controls the majors, but neither it nor any other drug influences the minor attacks. Occasionally free from minor attacks for a day or two, but more often they occur almost continuously for some hours.

No. 31 (A. H. M.). Male, aged 14. Family history clear. Physically and mentally normal. Many scars due to falling in attacks. First fit aged 7. Very frequent short attacks with loss of consciousness. Often falls. Rapid return of consciousness. May have a day or two free from attacks; on other days attacks are practically continuous. Bromide and luminal medication useless. ? A case of pyknolepsy.

No. 32 (A. G. M.). (See No. 11 above.)

We desire to express our indebtedness to Dr. H. D. Kay for his helpful advice upon many points. The expenses of the investigation were in part defrayed by the Medical Research Council and in part by the London Hospital Epilepsy Research Fund.

COMPLICATIONS AND MORTALITY OF APPENDICITIS.

BY RICHARD WARREN, M.D., M.CH. OXF.,
F.R.C.S. ENG.,
SURGEON TO THE WESTON-SUPER-MARE HOSPITAL; LATE SURGEON TO THE LONDON HOSPITAL.

APPENDICITIS, like many other evils, appears to be a by-product of our modern, high-speed, material "civilisation." At any rate, that is the impression left after reading the painstaking researches of Short[1] and others. In spite of the advances of surgery the total death-rate for the disease is not diminishing in this country, while in the United States it increased 30 per cent. in the first 20 years of the century.

TABLE I.—*Mortality per Million from Appendicitis* (Willis,[2] Adams,[3] and H. H. Greenwood[1]).

	U.S.A.			*British Isles.*				
Year ..	*1901*	*1911*	*1921*	*1913*	*1918*	*1921*	*1924*	*1927*
	110	120	144	69	66	72	74	70

The figures given in Table I. are not the same as the case-mortality and do not explain whether the disease is more common or whether it actually has a higher mortality. As it was rare before the latter years of the last century there can be little doubt that it is now more common. Is the increasing mortality in the country where the Ochsner treatment had its origin due to this expectant treatment? This seems hardly likely from the figures given by institutions where it is practised. More probably the disease has become more common or more severe in character.

Comparison with other Abdominal Urgencies.

Some years ago I investigated the results at the London Hospital, taking two periods of a few years each, first about 1900 and then about 1914. The percentage mortality was as shown in Table II.

TABLE II.—*Percentage Mortality.*

Year.	Appendicitis.	Perforated gastric ulcer.	Intestinal obstruction.
1900	27	66	50
1914	6	40	39

I ascribe the improvement to recognition of the importance of early operation and to better after-treatment, principally the use of Fowler's position. While the statistics for institutions have improved, the general death-rate from these diseases has not fallen proportionately. The figures given by Willis[2] for the United States and Greenwood[4] for this country are as given in Table III.

TABLE III.—*Mortality per Million.*

U.S.A.			*Great Britain.*			
Year.	Appendicitis.	Hernia and obstruction.	Year.	Appendicitis.	Hernia.	Obstruction.
1901 ..	110	130	1918 ..	65	64	81
1910 ..	120	120	1927 ..	70	50	64
1921 ..	140	106				

The falling mortality of intestinal obstruction is curious, for in hospital cases the improvement seems so small compared with that obtained for cases where the peritoneum is involved—viz., appendicitis and perforated gastric ulcer. During the same number of years I met 1000 cases of appendicitis and 150 of intestinal obstruction and had practically the same number of deaths in each group—viz., 50—which agrees closely with the published figures.

Case-mortality.

I should put the case-mortality at about 5 per cent. or rather more, judging from my own experience for the past 20 years and the results of other surgeons who give long series. An analysis of cases gives the impression that there is a great variation in the severity of the disease from time to time (Table IV.).

TABLE IV.—*Comparison of Case-mortalities.*

—	Cases.	Mortality per cent.	Date.
Grey Turner[1] ..	1339	6·7	1909–1929
McNeil Love[2]	607 expectant 2706 immediate	3·8 6·7	1920–1924
Gatch and Durman[3]	202	7·2	1924
Greenwood[4] ..	200	—	1927–1929
Warren	1072	6·0	1909–1929

Factors likely to affect the mortality are: (*a*) period, (*b*) age, (*c*) sex, (*d*) accidental complications, (*e*) severity of infection and natural complications, and (*f*) treatment.

(*a*) *Period.*—In my own cases there was a notable difference in series at different times (Table V.).

TABLE V.

Date.	Cases.	Bad cases (per cent.).	Secondary operations (per cent.).	Mortality (per cent.).
Pre-war, 1910–14 ..	433	9·2	3·5	1·3
War, 1914–17	268	10·4		7·4
Immediate post-war, 1919	164	11·4	6·5	8·7
Late post-war, 1921–25	187	9·6	1·6	4·8

The cases labelled "bad" were those with spreading peritonitis or intestinal obstruction or both. It is difficult to grade cases according to severity; the surgeon has to go partly by the general and local condition of the patient and partly by what he finds at operation. Since it is, as a rule, advisable to explore as little of the abdomen as is compatible with dealing with the mischief, it is often impossible to say how far the peritonitis has spread. Grey Turner, in a very interesting communication, reports 1339 acute cases, of which 110 had diffuse peritonitis or severe primary complications, such as intestinal obstruction or pylephlebitis, with a mortality of 33 per cent. He separated off groups of cases with flank peritonitis or localised abscess which, together with simple acute cases—i.e., those without peritonitis (1160 in number)—had a mortality of 2·9 per cent. My observations and notes are not accurate enough for such subdivision, but of 1072 acute cases there were 107 with diffuse peritonitis or obstruction or a combination of these, with a mortality of 41 per cent. The remaining 965, including abscesses, localised peritonitis, and simple inflamed appendices, showed a mortality of 2·6 per cent., which agrees closely with Turner's figures for this class of case.

The 1910–14 cases were consecutive at the London Hospital, as were the next group during the war. There is a higher mortality and slightly higher percentage of severe cases among the second group, and I suggest that this is caused by malnutrition and the absence of many abled-bodied patients who would probably have a lower mortality (see under Age). As a matter of fact, the latter would probably be cancelled out by the greater proportional number of women, whose resistance seems to be higher. The next group forms an interesting series. They occurred immediately after the war, when deficient feeding and the great influenza epidemic may have lowered the resistance of the nation. In addition the series includes practically all the night emergencies at the London Hospital for some months. All these factors together probably account for the poor results, for although the incidence of severe cases only showed an increase of 2 per cent. the patients responded badly to treatment, and there were severe and unusual complications, such as secondary hæmorrhage, wide sloughing of the abdominal wall, and an unusual number of secondary operations—viz., 6·5 per cent., compared with 3·5 per cent. for 1910–17.

The next series, for contrast, represents a practice in an agricultural district. The figures suggest a mortality about the same as that of London in peacetime, but the true mortality is lower, for amongst the nine cases which died the following things happened.

1. A woman who had had an acutely inflamed appendix removed without drainage had done well and was about to get up 14 days after operation when she became acutely ill with signs of some great abdominal urgency. Laparotomy revealed thrombosis of the inferior mesenteric vessels and gangrene and carcinoma of the sigmoid colon.

2. An old man of 65 with myocardial degeneration and fibrillation had an acute appendicitis with abscess. The appendix was removed, and the abscess drained and healed in a few days, but 10 days later, before he left hospital, he succumbed to his cardiac condition.

3. A girl of 6 developed a general peritonitis in 30 hours. At operation there was turbid fluid and lymph all over the intestines and the appendix was slightly inflamed; she died in a few days. It was probably a case of pneumococcal or streptococcal peritonitis, but in the absence of bacteriological evidence I felt obliged to include the case in the appendicitis series.

Excluding these cases, the mortality is a little over 3 per cent.

(*b*) *Age.*—Next to early diagnosis the patient's age is the most important factor affecting the mortality (Table VI.).

TABLE VI.

Age.	Cases.	Complicated cases.	Died.	Mortality per cent.
0–5	21	5	3	14
5–10	122	13	11	9·0
10–15	197	13	12	6·0
15–20	191	20	11	5·7
20–30	281	17	10	3·5
30–40	131	9	3	2·3
40–50	63	14	6	9·5
50–60	47	10	7	14
60–70	11	3	3	37
70–80	7	1	—	—

The mortality diminishes rapidly after the first decade and slowly falls until about the fortieth year, when it again rises sharply. It is curious, but probably only a coincidence, that none of the septuagenarians died. The reason for the greater mortality at the two extremes of life are: (1) The difficulty in diagnosis in children, in whom early appendicitis is often mistaken for dietary indiscretion and unfortunately often treated by parents with a purge. (2) The young also show an inferior resistance to acute infections—e.g., peritonitis. (3) The more elderly seem to have diminished sensibility, so that they take little notice of pain in the abdomen until their condition has become serious. The pain of an incipient appendicitis is probably less severe than that of an intestinal colic from some dietary lapse, and is disregarded. It is surprising how slightly persons of a certain age show the severity of the trouble either subjectively or objectively; for instance, a man of 58 was regarded by his doctor as a case of subacute intestinal obstruction as he had had neither increased pulse-rate nor fever for a week. Two days before I saw him he was relieved by an enema, shortly after which he began to have pain and distension. When I saw him he was distended, and my impression was that of a subacute obstruction which had become acute, probably because of a growth in the colon. Operation, however, revealed fibrino-purulent peritonitis and obstruction from a gangrenous appendix. Cases like this are unfortunately not uncommon, and have a high mortality.

TABLE VII.

Sex.	Number.	Died.	Mortality per cent.
Male	575	40	7
Female	480	25	5·

(*c*) *Sex.*—As might be expected, the female sex, with its greater power of passive resistance, shows a slightly lower mortality (Table VII.).

(*d*) *Accidental Complications.*—By these I mean accessory diseases which either lower the resistance or actually kill the patient, who may have practically recovered from his appendicitis. Mention has already been made of myocardial degeneration, thrombosis of the mesenteric vessels, and gangrene of the colon; to these may be added diabetes, perforation of a duodenal ulcer, and pulmonary embolism. Most of these cases should really be excluded, but it is invidious to make a distinction. These casual complications formed one-sixth of the total deaths.

(*e*) *Direct Complications.*—These are peritonitis, intestinal obstruction and combinations of the two, and are the important causes of death in appendicitis. Direct complications form a large percentage of the whole. In 1072 cases there were 107 direct complications—i.e., 10 per cent., and of these 44 died—i.e., two-thirds of all the deaths. It is often difficult at operation to settle the degree of spread of peritonitis. I have retained the term "spreading peritonitis" for cases where there was matting of intestines by recent lymph with loculated pockets filled with pus, more or less foul, together with redness and distension of the intestine. The type of case where there is merely turbid or semipurulent fluid, widely disseminated amongst the intestines, but without lymph and with but little redness or distension of the intestine (which clinically often suggest peritonitis) have not been included under this heading. Such cases mostly have a fairly smooth recovery, though they may pass into the more severe type. The rate of spread and virulence of a peritonitis cannot be measured in time, but only by the severity of the infection and the resisting powers of the individual's peritoneum. It is almost impossible to say whether a condition of local peritonitis is an early stage of a severe infection, which will probably advance rapidly, or a later stage in a condition which is to some degree held under control by the natural defences of the peritoneum. A good many cases of spreading peritonitis recover; my impression is that those which die are either late, owing to neglect or wrong diagnosis, or especially virulent infections—e.g., streptococcal cases.

Intestinal Obstruction.

These cases form an interesting group, to which insufficient attention has been directed. In 1924[8] I collected my cases and found that I had met 34 during a period in which I had seen 1011 cases of acute appendicitis, but some of the cases had followed operations by other surgeons. In the present series of 1072 patients there were 32 cases of obstruction or obstruction combined with peritonitis. In 1924 I reported 180 cases of obstruction; 68 were strictures, 40 intussusceptions, and 54 bands and kinks. Of the last group no less than 34 were directly due to appendicitis. I do not know how many I have missed and confused with peritonitis. During the discussion on my paper one surgeon of great experience stated that he had never met with the condition, which makes me think that it is often confused with peritonitis and paralytic ileus. The literature on this subject is not extensive; Harrigan[9] describes 8 cases, of which only 3 were immediately post-operative; Rayner[10] notes 3 cases out of 126 cases of appendicitis; Carlson and Marshall[11] among 875 cases of appendicitis found 15 cases of obstruction, of which 8 were immediately post-operative. They make the pertinent remark that possibly a good many cases labelled "acute dilatation of the stomach" are really obstruction of the small gut by lymph bands and peritonitis.

Clinically cases of obstruction due to appendicitis fall into two main groups: (1) primary, and (2) post-operative; the latter may be further divided into immediate and late. By immediate I mean cases which demand attention whilst still in hospital for the primary operation. The late post-operative cases may occur weeks, months, or years after the operation or attack of appendicitis and do not come into the discussion here, though they form a notable percentage of all cases of obstruction of the bowel due to bands and kinks.

Primary Obstruction.

As a rule the whole affair is recent and acute; the symptoms are like those of acute obstruction, but probably with some fever and localised tenderness and resistance in the right iliac fossa, suggesting something more than a simple obstruction. Of this type the following is a good example:—

A woman aged 70 had been ill for 24 hours with repeated vomiting, abdominal distension, and constipation. The temperature was subnormal, the pulse normal, and the right iliac fossa tender. Laparotomy was performed immediately, and showed an acutely inflamed appendix adherent to and kinking the lower ileum, with marked distension of the gut above and emptiness below. Removal of the appendix from its lymph bed automatically released the gut and the patient made a good recovery.

A similar clinical picture may be produced by *cancerous obstruction of the lower colon* with distension of a cæcum, which is becoming ulcerated and perhaps beginning to leak. In middle-aged or elderly persons the distinction between these two conditions is extremely difficult. The following is a less common type:—

A boy aged 8 suffered from belly-ache and occasional vomiting for a month. His appetite was bad, his temperature irregular, and he sweated at night. For two days before I saw him the vomiting had been more urgent and the bowels confined. When seen he had a typical abdominal facies, marked distension of the abdomen, and visible peristalsis of small intestine; his temperature was 100°F. and his pulse-rate 100. Laparotomy was done immediately, and it was found that two or three feet of the ileum immediately above the cæcum were kinked and matted by adhesions. The ileum above was dilated and the colon below collapsed. An acutely inflamed appendix was removed from the middle of the matted coils of intestine and adhesions broken down. As it was uncertain whether the intestinal contents could pass along such a length of damaged intestine, a lateral anastomosis was made between the ileum, above the kinked part, and the cæcum. A valvular cæcostomy was done at the same time and the patient made a good recovery.

Post-operative Obstruction.

This type is pathologically similar to the last, but in addition there is frequently suppurative peritonitis —i.e., pockets of foul pus between adherent coils of intestine. Clinically, in my experience it is commoner and more fatal than the primary variety. The danger is in part due to the greater difficulty of diagnosis, for it is not easy in the early stages to distinguish atonic ileus or early-spreading peritonitis from obstruction caused by a recently formed lymph band. This is partly because the patient has been ill longer and has already been through one operation, so that his vitality is depressed. Complete diagnosis may not be easy, but is less important in the primary cases, since in these it is usually fairly clear that the condition is one of abdominal urgency with signs pointing partly to obstruction and partly to some inflammatory affection, and immediate operation is definitely indicated. The main point is to open the abdomen by the paramedian rather than the iliac incision, so as to give plenty of room if adhesions have to be dealt with or an anastomosis formed.

In the post-operative type diagnosis may be difficult and is extremely important, for, on the one hand, a true mechanical obstruction has to be relieved, and, on the other, inflamed intestine should not be handled and abused if the condition is really a simple peritonitis. The sudden onset of paroxysmal abdominal pains, with rising pulse-rate and falling temperature, in a patient who has been going on smoothly after the original operation is suggestive. When associated with bilious vomit, becoming brown, and a soft abdomen, there is almost certainly obstruction, and there should be little hesitation in operating. Visible peristalsis of the small intestine is, of course, decisive, but to wait for its appearance is to incur grave risks, for it occurs late in the more acute obstructions. Where there is a mixture of obstruction with suppurative peritonitis, diagnosis and treatment are alike difficult, but I cannot help thinking that in some cases expectant measures are adopted when operation would be better.

The following is a fairly typical example:—

A boy of 17 who had been ill for one day was operated on and a gangrenous appendix was removed; there was foul pus in the pelvis, which was drained. Three days later, after good progress, there was severe abdominal pain and vomiting, but an enema gave relief. The next day, as pain and vomiting recurred, the abdomen was opened and the small intestine was found distended above a mass of matted intestine with pockets of pus. The adhesions were freed, a valvular ileostomy with catheter was made in the ileum above the obstruction, and a pelvic drain was reinserted; the patient made a good recovery and was out in a month. Catheter drainage of the ileum in such cases is a life-saving measure and the wound usually heals up in two to three weeks at the latest.

I cannot help thinking that some of the cases called "post-operative obstruction" really had obstruction at the start, but, owing to the small amount seen at operation, obstruction was missed. In the worst class of case the surgeon is on the horns of a dilemma, since too much zeal in breaking down adhesions may spread infection further, yet adhesions must be freed if they cause obstruction.

(*f*) *Treatment.*—We are all agreed that the diseased appendix is best removed, but there is some diversity of opinion as to when exactly this is best done. The main point at issue is the treatment of cases which have been in progress some time, for practically all surgeons admit that in early cases immediate appendicectomy is the safest course. In cases which have lasted some time the bulk of surgeons advocate immediate operation in almost every case, but there is quite a considerable school which adopts expectant measures based on the teaching of Ochsner. These consist mainly in placing the patient in the Fowler position, giving no fluid by mouth, but only rectal saline as nourishment, and possibly also morphia, but only operating if the condition becomes worse. Very good results are claimed by the advocates of this method, but it must be remembered that cases so treated are to some degree selected and very possibly include only those which would have done equally well if operated on immediately. Unless the figures include all the appendicitis cases met with over a reasonably long period the conclusions are not sound. Adams[3] gives the following figures for comparison, quoting Love's statistics for the London Hospital (Table VIII.).

TABLE VIII.

—	*Cases Treated Expectantly.* No.	Died.	Mortality per cent.	*Cases Treated by Immediate Operation.* No.	Died.	Mortality per cent.
London Hosp.	341	12	3·5	1677	95	5·5
St. Thomas's..	211	9	4·2	901	76	8·4

Adams points out that in the latter series there were over 400 cases of general peritonitis with a mortality of 20–30 per cent., and raises the question whether the series treated expectantly contained the same proportion of severe cases—i.e., whether it was a straight series without selection. Deaver and Magown[11] give copious statistics from the Lankenau Clinic from which I quote a few figures.

Of 5488 operations for acute appendicitis, from 1901 to 1919, 327 died.

1901–05	..	Mortality percentage		..	..	10·5
1906–10	..	"	"	..	..	5·6*
1910–15	..	"	"	..	..	3·7*
1915–21	..	"	"	..	..	4·2*

* Ochsner treatment adopted.

In 1918 the mortality was 5·2 per cent., showing the same increase from war and influenza that I found in my own cases. Ashurst[12] gives an account only of severe cases—i.e., those which were drained, as follows: immediate operation, 210; mortality, 10 per cent.; delayed operation and Ochsner treatment: mortality, 35 per cent. Of the latter group, six cases died without any operation, being too ill for it.

Ashurst gives a useful hint about the diagnosis of diffuse peritonitis—viz., that rigidity alone is often associated with the presence of an exudate of turbid fluid in the peritoneum, which is relatively innocuous and often does not need drainage, but if distension is present as well there is probably a definite fibrinopurulent peritonitis. He shrewdly adds that surgeons who practise delay may claim as successes due to delay cases which would do equally well if treated by immediate operation; "only those who look inside the abdomen can know the true condition of affairs during the acute stage." Willis[2] quotes Ochsner as having a mortality of 4·5 per cent. in the early years of the century and one of 2 per cent. in 1924, but gives no details of the number of cases and whether they were a straight sequence.

The advantage claimed by the upholders of expectant treatment over immediate operation seems therefore to be not more than 2–3 per cent., which is less than the differences I have found in my own cases, all treated on very similar lines in series occurring at different times, so that it is hard to believe that waiting is any great advantage. Love,[4] who advocates expectant treatment, does not seem wholly wedded to this method, as he states that in general peritonitis appendicectomy is advisable if possible. It is clear that the cases treated on expectant lines are selected cases and not a straight series. In the same way a surgeon might claim that drainage is bad because the mortality of drained cases is 10 per cent., while of undrained it is about 0·75 per cent.

Time of Election for Operation.

A good deal of stress has been laid upon the danger of operating at a certain period of the disease. This is put variously; perhaps the most usual is to regard the third to fifth day as the time to avoid operation. Personally I find the disease advances with very varying rapidity; some cases are no further advanced in three days than others in 24 hours. Some have spreading peritonitis after a day; others after a week have little but lymph round the inflamed appendix. There can be little doubt that many patients do not notice the earlier symptoms or put them down to dietary indiscretions, and only seek advice when the appendix is perforated or a localised abscess has burst and the condition is serious. Adams[3] remarks that there may be marked pathological changes in an appendix which causes no pain at all and may certainly give rise to no vomiting; if so, the patient may easily make an error of 48 hours in the length of the history he gives. With this view I entirely agree. The expectant method demands enormous care in watching for any adverse symptoms which may suggest immediate operation. Pulse-rate and temperature will have to be taken two-hourly and the abdomen must be frequently inspected; even then mistakes are easy. One case of this type always recurs to me.

At a children's hospital the resident one morning said to me: "I wish you would see a child who, I thought, had appendicitis last night, but to-day I am not at all sure about it, and think I may have been mistaken." I examined the boy and could find no tenderness or rigidity of the abdomen; there was no pain and the pulse and temperature were normal. Knowing the resident to be a careful man I replied: "Although I can find no signs now, since you found them last night I believe it is wisest to operate." I did so, and found a completely gangrenous appendix with little or no effusion. The child made a speedy recovery; waiting might have meant disaster.

I have met with many similar cases though seldom quite so dramatically. Another danger arises from mistakes in diagnosis. I well remember a former colleague of mine telling a story against himself. He had decided to adopt the plan of waiting between the third and fifth day in cases of appendicitis with a mass in the right iliac fossa. The first case on which the plan was tried proved to be one that did not improve; so laparotomy was done next day and revealed an intussusception. A twisted ovarian cyst may mislead in the same way, though this is a less serious error. A distended and leaking cæcum above a cancer of the colon, or a slowly leaking duodenal ulcer, might be mistaken for appendicitis, with disastrous results if the patient be treated on expectant lines.

I feel that one cannot judge the condition of the appendix with sufficient surety by the clinical progress of the case, for the condition found at operation is frequently more severe than would be expected from the physical signs. (The converse also is true, but of less consequence.) Expectant treatment can only be used in institutions where the patient is constantly under skilled observation, and even then it may have to be given up for active measures, with loss of valuable time and additional danger. My impression is that delay should only be practised where conditions are very unfavourable for operation, either because the patient has some additional disease such as pneumonia, nephritis, and diabetes, and the appendicitis does not appear to be severe, or where the local conditions, as at sea or far from civilised appliances render the success of any operation problematical.

Scope of the Operation.

It is very important to consider how much should be done in the more severe cases. It is just as important not to do too much as to do too little. In the earlier cases the appendix can usually be removed with little difficulty, but where the disease has been present for some time it may be wiser simply to drain any abscess (it should be noted that it is easy to miss loculations of pus, where more than one are present) and leave the appendix for a future operation, I find that I fail to remove the appendix in about 1 case in 20. Judging from the remarks of Love, some surgeons are too anxious to remove the appendix at all hazards in every case, and thus sometimes do harm by breaking down adhesions and spreading infection. If the appendix does not come to hand in about five minutes, it is best to be satisfied with opening the collections of pus in cases where the adhesions are many, dense, thick, and œdematous. The only reason for going further is the relief of obstruction, where this is present, by division of adhesions and possibly by cæcostomy or ileostomy. Except in the more difficult cases such an operation will not take more than 10 to 15 minutes and may not take more than five.

The Incision.

This will depend on the type of case and the habits of the surgeon. The muscle-splitting, paramedial, and pararectal lines of approach all have staunch advocates, and I note that Grey Turner[8] recommends muscle-cutting in the right iliac fossa for cases where drainage is needed. I was not impressed with the results of this method which I used to see when I was house surgeon, and I determined never to use it. In those days it led to trouble from vomiting and prolapse of intestine. But this may have been due to the use of heavy gauze packs as well as to the type of incision. I have made more use of the muscle-splitting incision than any other, but where the diagnosis is uncertain or complications, such as obstruction are likely, and in women, I frequently employ the paramedial, displacing the rectus muscle outwards. Some surgeons think that drainage through the muscle-splitting incision is poor, and suggest a suprapubic stab, but I have not been struck by any great advantage in this. In about 4 per cent. of all cases in this series there was need for a secondary operation for draining a residual abscess or for obstruction. The advantages of an incision in the right iliac fossa in the early definite cases are obvious, as there is far less risk of spreading infection amongst the small intestines; moreover, it is much easier (and therefore safer) to reach the appendix, and by extending the splits in the layers of muscles widely a very free exposure can be obtained. Where the condition is advanced the problem is somewhat different, as the surgeon must be able to cope readily with pockets of pus disseminated amongst the coils of small intestine and to relieve any mechanical obstruction. The nicest judgment is needed if he is to exert the right amount of interference in these patients, for in one case the adhesions may be walling off infection from susceptible areas and in another a quite recent and apparently delicate band of lymph, which is broken by a touch, may be obstructing a loop of ileum quite as effectively as an organised fibrous band. He should keep a very sharp look out for coils of distended small intestine, and if, when he has broken down lymph bands, the coils do not readily empty into the lower intestine, a valvular enterostomy may save life and be useful both for the administration of saline and the evacuation of gas and liquid fæces.

Drainage.

The percentage of cases drained is some criterion of the severity of the series, but allowance must be made for the predilections of individual surgeons, whose ideas of when to drain vary considerably. Greenwood,[4] who must be congratulated on recording the most successful series of cases, gives the impression that he drained only 18 per cent. and that Grey Turner drained 26 per cent. (My interpretation of the latter's communication is that more than half were drained, and expresses surprise that Flint records 1080 acute cases from Leeds, of which presumably half required drainage. I have drained about half my cases. All this goes to support my view that appendicitis varies in severity from causes associated with time and place. Greenwood advocates draining through the loin when pus is present there. This sounds reasonable, but in my earlier days I remember seeing this done fairly often and always being struck by the way pus refused to come out of a loin tube, even when the patient was lying on his back (I refer to the days before Fowler's position was employed), while it came readily through a tube in the right iliac fossa. Consequently I have never employed this mode of drainage.

Drainage through a muscle-splitting incision is said to be bad, but I have not found it so. In about 4 per cent. of my cases a secondary operation was needed for residual abscess or obstruction, and, while it is true that some of these were in patients operated through the right iliac fossa, others had been done through the paramedial route. My usual plan is to keep a tube down into the pelvis (when this needs draining) for two days and then shorten the tube, so that it just goes through the abdominal wall; I usually omit it about two days later. If the tube comes out too early a residual abscess may form, but if it is left in too long the pressure may cause a fæcal fistula. More than one-third of the cases of obstruction occurred before any operation was done, but the possibility of a drainage-tube causing *complications* such as obstruction makes it important to take the tube out as soon as possible.

Conclusions.

1. Appendicitis appears to be developing a more severe character or is more common.
2. The disease shows a considerable variation in its severity, depending on time and place; the mortality in my experience varies from 3 to 10 per cent.
3. Expectant treatment may give good results in certain hands, but as a general measure its advantages are not proved and its wide adoption might lead to further disasters. The mortality is greatest in children, who are certainly not cases for expectant treatment, owing to the rapid and insidious way in which complications, such as peritonitis, develop in young subjects, and their liability to acidosis from starvation.
4. Early diagnosis and immediate operation are the counsels of perfection, but failure to diagnose early is by no means always the fault of the practitioner, for in children and old people the diagnosis may be quite difficult, and many persons regard a stomach-ache too lightly and do not send for the doctor till they have developed a well-marked peritonitis.
5. The main causes of death are peritonitis and mechanical obstruction; the latter can be very largely prevented by suitable technique at operation, and a careful watch should be kept for this important complication.

Clinical and Laboratory Notes.

ACCESSORY SPLEEN WITH RECURRING TORSION OF ITS PEDICLE.

BY R. CHARLES ALEXANDER, F.R.C.S. EDIN.,
LECTURER IN CLINICAL SURGERY IN THE UNIVERSITY OF ST. ANDREWS; SURGEON, ROYAL INFIRMARY, DUNDEE.

CASES of accessory spleen giving rise to symptoms which call for surgical interference are rare. In 1914 I published, with Archibald Romanes, a paper[1] recording a case which came under our observation and giving a short review of similar cases from the literature. The interest of the present case is enhanced by the fact that, owing to its resemblance to the former case, a correct preoperative diagnosis was made.

A housewife, aged 35, was admitted to my wards in the Dundee Royal Infirmary in June, 1929, on the recommendation of Dr. J. Wilson of Anstruther. She complained of recurring attacks of pain in the abdomen, and of a lump, which she had felt in various situations in the abdomen. The pain was of a burning character and the attacks lasted about three days. During the two years previous to admission, the interval between the attacks had gradually diminished from six to two months. The pain was situated above and to the left of the umbilicus, and usually came on when she was tired; it was more severe if it coincided with a menstrual period. It was not accompanied by vomiting, but there was sometimes a feeling of nausea when she stooped. During the attacks of pain she had felt a lump in the upper abdomen "about the size of a small orange," and she volunteered the statement that the lump was larger during the menstrual period. Between the attacks she felt well; there was no dyspepsia, and the bowels moved freely. She had lost weight during the preceding four months. There was a family history of tuberculosis, and after the birth of her first child some years ago she had had a bilateral pleural effusion which had taken some time to clear up.

She was a woman of poor physique and looked rather tired. The abdomen moved freely, and from time to time one could grasp a firm spherical tumour, about the size of a tangerine orange. It was tender to touch and could be moved rather freely about the abdomen. There was no ascites and the percussion note showed no enlargement of the liver or spleen. Rectal examination was negative. Radiographic examination with and without barium failed to reveal any abnormality in the alimentary tract. The blood count showed some increase of the red cells—viz., 6,050,000.

I was encouraged by the resemblance to the former case to make the preoperative diagnosis of accessory spleen with recurring torsion of the pedicle. The possible alternatives were an omental cyst, or a mass of tuberculous glands. The latter would possibly have shown calcified areas in a radiogram. The increase in size of the tumour during the menstrual period suggested that it was of glandular origin.

On June 13th laparotomy was performed under general anæsthesia. A perfectly spherical red tumour was found attached by a thin pedicle about three inches in length to the centre of the anterior aspect of the gastro-hepatic omentum, the pedicle allowing the tumour to swing freely in the abdomen. The pedicle was ligated and the splenculus removed. The spleen was normal in size and position, and no other splenculus was detected. The other abdominal viscera were normal, except the appendix, which was long and buried in adhesions. This was removed and the abdomen closed. Recovery was uneventful.

It seems probable that up to two years before the operation the splenculus was sessile and gave rise to no symptoms, their onset being determined by the formation of the pedicle, torsion of which produced congestion in the organ with resulting pain. Prof. L. R. Sutherland reported that the section on microscopic examination showed the appearance of normal spleen; there was no evidence of hæmorrhages or fibrosis, as was seen in the specimen from the previous case.

Since the publication of the previous paper, I have sometimes noted the presence of small splenculi at operations. None has been larger than a filbert. I have occasionally found them in relation to the greater curvature of the stomach when I was performing partial gastrectomy frequently in the pedicle of the spleen near its hilum, and occasionally in the great omentum. I have seen no record of other cases similar to the two I have recorded, but R. Finaly[2] notes the presence of an accessory spleen in the sac of a left inguinal hernia, the spleen being attached to the upper pole of the epididymis. He quotes a case reported by Sneath where an accessory spleen simulated a third testis and was connected by fine cord-like attachments to the normal spleen.

THE USE OF BONE-PLATES IN THE TREATMENT OF FRACTURES.

BY H. H. GREENWOOD, M.B. LOND., F.R.C.S. ENG.,
CONSULTING SURGEON TO THE GREAT WESTERN RAILWAY HOSPITAL, SWINDON.

DURING 1920, when I was visiting surgeon on the staff of the Orthopædic Hospital, Beckett Park, Leeds, I used bone-plates and bone-pegs in six cases of ununited fracture of the humerus and showed the later successful cases at the Leeds and West Riding Medico-Chirurgical Society. The idea originated in a paper by Gallie and Robertson,[3] although Hey Groves[4] had previously used bone-plates fixed by metal pegs in a somewhat similar manner. To avoid the elaborate and tedious manufacture of bone-screws with the tapping-out of corresponding holes in the bones, I used bone-pegs square in section and tapering slightly. I found that these grip sufficiently firm to hold the fractured ends in good apposition and can be expeditiously inserted. I have continued to use them for certain cases ever since and find that their sphere of usefulness lies mainly in the more deeply seated fractures, where a subsequent operation for the removal of a metal plate which has, so to speak, outworn its welcome, is a serious undertaking. For the more easily accessible

Bone-plates and pegs.

fractures, such as those near the distal end of the radius, ulna, or tibia, the metal plate can still claim advantages which scarcely need emphasising.

The accompanying photograph illustrates plates and pegs. The pegs are shown inserted in the upper plate in position, but they are too large for the holes and should sink through for about three-quarters of their length. After being driven home the projecting ends are nipped off with sharp bone-forceps and the rough end filed down level with the plate. Care should be taken not to use too powerful a blow when driving in the pegs, lest the plate be split. The bone-plates are slightly hollowed on the under surface to allow of close apposition to the bone. Both plates and pegs are prepared as Mr. Hamilton Bailey[5] directs, that is, by boiling for 20 minutes on three successive days. Their strength is apt to become impaired by too prolonged boiling.

A CASE OF SPASM OF THE CERVIX UTERI.

By L. J. Green, M.R.C.S. Eng.

I should like to know whether the following case is to be regarded as exceptional.

The patient, aged 25 and healthy, had had one previous uneventful confinement, and was first seen in labour at 8 A.M. The abdomen was much distended, the os four-fifths dilated, the membranes bulging but unruptured, and no part could be felt presenting. Pains, felt only in the lower abdomen, were occurring every three minutes. The patient, having had no sleep, was tired out, labour having commenced at 6 P.M. on the previous evening. She was of a babyish type with small power of endurance and control, moaning and crying for help. The fœtal heart was heard beating to the left of the umbilicus. At 10.15 A.M. the condition of the os and membranes was unaltered, but the head could be felt presenting and the pains were stronger and felt in the sacral region.

At 1 P.M. the patient was screaming for "help," with such phrases as "take it from me." As the os seemed fully dilated and the patient was much exhausted and the abdomen was distended, it was deemed advisable to rupture the membranes. After doing so the hand was temporarily withdrawn from the vagina and the patient immediately re-examined to determine the exact presentation. I was astonished to find that the os was now only two-fifths dilated, the sensation imparted to the fingers unmistakably suggesting considerable muscular tone. I was so astonished that I examined the patient with unusual persistence and deliberation. It seemed certain that the previous diagnosis of full dilatation of the os must have been mistaken and that the patient was in reality in the early part of the first stage of labour. In view of her sleepless night and her poor psychological make-up I decided to adminster a sedative. She was informed that delivery was some distance ahead, advised to compose herself, and given omnopon gr. ¼ hypodermically, whilst a hot enema was ordered to clean out the bowel, which was discharging a little fluid fæces with each pain. The fœtal heart was then heard beating one inch below and to the left of the umbilicus.

At 2.15 P.M. there was an urgent telephone message. A live, male child of 8 lb. had been born precipitately.

The only explanation of this case appears to be that following the manual rupture of the membranes, the cervix went into an unusually strong spasm which rapidly passed off. It is, of course, conceivable that I was mistaken (1) in the diagnosis that the os was fully dilated, made before rupture of the membranes; (2) in the diagnosis made after rupturing them that the os was only two-fifths. These possible errors can be eliminated (*a*) because the os was four-fifths at 8 A.M. and 10.15 A.M., (*b*) because of the particularly careful examination after finding that the os was two-fifths.

The spasm of the cervix may have been a neuromuscular disorder due to a sleepless night, the patient being restless, weak-spirited, terrified, very fat and uncomfortably distended abdominally. But more remarkable than the sudden onset of the spasm is the rapidity, as acute as its onset, with which it must have subsided, with most humiliating sensations on the part of the obstetrician, who was not equal to the intellectual emergency and whose judgment must have seemed so wide of the mark. Was this rapid subsidence of the spasm of the cervix due, one wonders, to the omnopon and connected with the patient's immature psychological status?

Medical Societies.

MEDICO-LEGAL SOCIETY.

At a meeting of this Society held on June 27th, Sir William Willcox took the chair, and Dr. E. Temple Gray read a paper entitled

The Medico-Legal Expert in France.

The difference between the status of the *médecin légiste* and that of the medico-legal expert in England was, he said, essentially due to the wide difference in legal procedure between the two countries, and especially to the difference in the position of witnesses. Crime was investigated by the officials of the Parquet, which was a department of the office of the Ministère Publique, and was so-called because they sat at a table below the bench, on the floor of the court. It was possible for the prosecutor to find himself, later on, on the bench to try the case with the earlier stages of which he had been concerned. All the evidence was heard in the form of statements, which were not taken on oath, and were known as *procès verbaux;* no oral evidence was heard until the actual trial before the superior court. When the case opened before the Cour d'Assise, the clerk read over the charge, the Ministère Publique might open, and the witnesses answered their names and retired to a separate room. They gave evidence, but could not be interrupted; they made speeches. The object of this procedure was, in theory, that their evidence should be spontaneous. In practice, however, they had plenty of time to prepare it. A witness might change a statement which he had made before the Parquet, and the court might listen to hearsay. Journalists, politicians, and professors of philosophy were in special request as witnesses. Cross-examination, as understood in this country, was quite unknown. Witnesses for the defence were heard, and the defending counsel spoke last. There was no summing-up, but the questions for the jury were agreed by both sides or fixed by the court.

Whereas medical witnesses in England enjoyed the same privileges and disabilities as other witnesses, in France their position was laid down specially in the civil code. *Médicins légistes* were organised into panels, which were composed of specialists in various departments of medicine, who need not possess the Diploma of Legal Medicine. The panel also contained a large number of men who in this country would be police surgeons. Besides this peculiar status, the medical witness in France had another privilege; the civil code imposed on him a very stringent *secret professionel.* The medical man was the first person mentioned in this provision, which gave a schedule of professions whose members were forbidden to divulge confidences they had received in their professional capacity. A third factor contributing to the authority of the medical witness was the great importance which the court attached to the written reports of evidence, and the small part played by oral testimony. These *procès verbals* were not verbal, but survived from mediæval times, when the police and other officers of State were unable to write. French law defined a large number of functionaries who were allowed to make verbal reports, which were accepted without question in a court of law.

The medical expert was, for all practical purposes, called by the judge; he was named in much the same way as an English coroner named his autopsist. An expert "committed" to make an inquiry signed a declaration before the *juge d'instruction* that he would report on faith and conscience, and on his report, upon which he would probably not be cross-examined, depended the technical evidence which would come before the court. He was invited to say whether responsibility attached to any person, and whether any action should be taken on the preliminary police inquiry. In a case of rape, for instance, he might be asked to describe the signs of the victim's resistance, and when insanity was pleaded in defence he would report on the responsibility of the accused. If two alienists decided that an accused person was not responsible, their report would be more or less conclusive.

---

[5] Bailey, Hamilton: The Lancet, 1929, i., 820.

The Medico-Legal Institute of Paris.

In 1903, the old Morgue had received the name of the Medico-Legal Institute, partly in deference to popular prejudice, and partly because the serious teaching of medical jurisprudence began there in that year. The present building, a splendidly equipped affair, had been opened in 1923. The bodies of all persons who died in Paris under circumstances requiring investigation—roughly 2000 every year—were sent to the Institute, which was also the centre for all medico-legal inquiries and examinations for workmen's compensation. The finances were rather complicated, as they were divided among three bodies; the first two would roughly correspond to the Home Office and the London County Council, and the third, the medical faculty, had no counterpart in London. The building was organised into two departments. The first, which was more or less deserted, contained what was ominously called the reception room; the autoclave, for disinfecting the clothes of the bodies; a large *vestière*, in which all bodies were classified; and spacious refrigerating cellars where they were stored. Refrigeration was performed by an ammonia plant which only needed to be worked for six hours a day. Bodies were kept at about 10 degrees of frost before examination and at freezing-point afterwards. This provision greatly assisted the autopsist. Small refrigerating safes were provided for viscera and fœtuses. There were also a waiting-room and chapel. The second, the busy part, held the headquarters of the medico-legal school and the departments of identification, pathology, and toxicology. It contained post-mortem rooms; pathological, toxicological, and research laboratories, a library, and a museum. The Dean of the School presided over the *Service d'Identification*, which did for the police much work not necessarily performed by teaching authorities in this country, consisting roughly of the identification of weapons, clothes, and other material. The scientific side of the institute was presided over by the municipal authorities, who had full control of the material. In contrast to the practice in England, an expert who was not on the teaching staff could not perform autopsies in this department, and the students therefore lost the advantages of his experience.

Dr. Temple Gray referred to the special committee of the Medico-Legal Society, which had been appointed some years before to consider and report on the possibility of founding a similar institute in this country, and suggested that it should resume its work.

Discussion.

Dr. LETITIA FAIRFIELD said that the committee of the Society had left the situation in an unsatisfactory position, but that the obstacles to the plan were not always realised by the public. The first difficulty was the position of the coroner in this country. The coroner's court was a magnificent institution, but it would be difficult for a medico-legal institute to collect all the material into one centre, and have it examined and dealt with by experts under the authority of the criminal court, without encroaching on the province of the coroner. The second difficulty was constituted by the very complicated organisation of the University of London. Edinburgh and Glasgow, in which medical instruction was centralised, possessed excellent medico-legal institutes. In London, however, the concentration of teaching material in one centre would immediately create difficulties with the many medical schools. The third difficulty lay in the very intricate relations between the London County Council and the coroners' courts in the various boroughs. The fact, however, remained that there was a great need for a medico-legal institute in this country, not only to concentrate the best teaching of medico-legal methods, but also to ensure that crime should be dealt with in the most scientific and up-to-date manner, which, whatever the public might think, was not the case at present. All these difficulties were simple questions of organisation, and could be overcome. The real trouble was that it was nobody's business to defray the initial cost. To create an institution similar to that of Paris would require a considerable capital sum, and none of the various bodies concerned—the Home Office, the London County Council, and the University of London—felt sufficiently interested to justify the expenditure. If some great philanthropic donor could be induced to realise the vital importance of this project to British medicine, the other obstacles would very soon be overcome. This country performed some of the finest medico-legal work in the world, but instruction in the subject was not organised, and encountered unique barriers. Dr. Fairfield hoped that the committee would spare no pains to produce a solution.

Dr. E. MACNAMARA asked whether the defence also was allowed, under French law, to call expert witnesses, whether they were subject to cross-examination, and what importance was attached to their evidence as opposed to that of the official experts.

Mr. E. R. BOLTON suggested that the scope of the medico-legal institute should include the work of the analyst, which was closely allied to that of the doctor but was very little studied from the legal aspect. He felt that cross-examination was a vital part of expert evidence, and produced the most valuable testimony.

Mr. E. HINKS agreed with Mr. Bolton on the importance of the chemical side of medico-legal work. He quoted the remark of a legal friend that, in practice, everybody concerned in an English criminal trial knew the criminal's record, and suggested that in reality the English procedure might therefore not differ greatly from the French, in which the prisoner's antecedents were made public at the opening of the case.

Mr. A. CREW declared, on the contrary, that the jury, who had to decide the facts, did not know the prisoner's record, and that if they ascertained it by accident the trial was generally held to be invalid. He remarked that in this country the medico-legal expert was usually regarded with suspicion—in many cases rightly so—and inquired how he was regarded in the public opinion of France.

Sir BERNARD SPILSBURY corroborated Dr. Fairfield's exposition of the difficulties in the way of founding a medico-legal institute in London. When the institute came into being—for he regarded its foundation only as a matter of time—a fresh difficulty would arise, that of planning a building and an organisation for a volume of work which was now very difficult to estimate, but which would certainly be three times as heavy as that of Paris. It was hard to see how a large enough expert staff was to be recruited. There would, however, be little difficulty in centralising inquests, for recent legislation had permitted the transfer of a body from a coroner's court to any suitable centre for investigation. It would be impossible to model an English institute upon any given continental one; the organisation would have to grow from small beginnings along lines dictated by conditions in this country. Any institute would be an improvement on the present unsatisfactory procedure, which kept medico-legal experts out of touch with workers in other branches of medicine. It was, however, useless to consider the question until the financial problem had been solved, as, from the cost of foundation, the expenses of the institute would have to be defrayed for the first few years. It would be impracticable to house the institute in any existing building, such as a discarded poor-law infirmary, for its work could only be carried out in a building specially designed for the purpose. Until the general public appreciated the necessity for an institute, or some serious disaster occurred, it was unlikely that any Government would take up the matter.

The CHAIRMAN inquired whether, in Dr. Temple Gray's opinion, the accused in France had such a fair chance of receiving justice—or of being acquitted—in France as in England. Reports of *crimes passionels* suggested that many persons were acquitted who would certainly be convicted in this country. He doubted whether teachers of forensic medicine in London could find the time to travel to a central institute.

Dr. TEMPLE GRAY, in his reply, stated that the French prisoner received equal justice with the English. Getting justice and being acquitted were not the same thing. French juries were very lenient, and their sentiment tended to balance any bias which the procedure might give to the prosecution. The jury might send for the President of the Court to inquire what effect their recommendation to mercy would have on the judgment. In addition to the official experts, it was the custom to nominate others of a lower standing to check their work. These, although not officially called by the prisoner, substantially assisted in his defence. The judge might ask an expert to attend and explain his report—rather an ominous invitation. Given the right teacher, a medico-legal institute could be started in a shed; the first toxicological bureau in Paris was housed under thoroughly insanitary conditions in the old Morgue. The future London medico-legal institute should start from the same small beginnings. The French were one of the most economical people in the world, and if they could afford an institute this country could, but the project would not be realised by the provision of a large sum of money. The first step towards a solution was to consider the manner in which the various institutes of the world had overcome their difficulties. It was essential that the medical profession be corporately represented on the managing board. Medico-legal experts in France were, on the whole, estimated by public opinion at their individual value. Dr. Temple Gray ended by pleading that, when the proposed institute was founded, the Medico-Legal Society should take a fitting part.

ROYAL SOCIETY OF MEDICINE.

SECTION OF UROLOGY.

A MEETING of this Section on June 27th, with Mr. SWIFT JOLY in the chair, was devoted to cinematographic demonstrations of three operations—prostatectomy, litholapaxy, and urethrotomy—performed by Sir John Thomson-Walker. The last of these films was accompanied by a talking film, a clearly enunciated description being given as each step of the operation was undertaken. The meeting, a large one, showed high appreciation of the demonstration, and this was expressed in a few words by the PRESIDENT.—Mr. FRANK JEANS, Mr. F. E. FEILDEN, and Mr. F. M. LOUGHNANE commented on details, after which Sir JOHN THOMSON-WALKER expressed his thanks for the assistance he had received from Mr. C. P. G. Wakeley, to whom he was indebted for the idea, and from the staff of the Department of Urology, King's College Hospital. The spinal anæsthesia had been given by Mr. Cecil Hughes. He could not speak highly enough of the work of the Medical Department of the Kodak Company. They had provided conditions under which a student could sit and quietly watch operations much more easily than if he was present in a more or less crowded operating theatre. The sound reproduction was carried out by the His Master's Voice Company, and hearers would judge of its success; if there were faults, they were faults of the speaker, not of the reproducer. An important question was, what was the value of moving pictures from the educational standpoint? He thought the profession was on the threshold of a good deal of change in this respect. It was well known to be impossible to show every student every sort of case or every sort of operation, but this new method enabled him comfortably to see and study half a dozen in an afternoon. Thus, he was sure, the means at the disposal of the Universities and teaching hospitals would be supplemented—he did not say they would be entirely changed—by this combination of moving picture and sound reproduction.

Sir John Thomson-Walker was cordially thanked.

Reviews and Notices of Books.

BIBLIOTHECA OSLERIANA.

Collected, arranged, and annotated by Sir WILLIAM OSLER. London: Humphrey Milford, Oxford University Press. 1929. Pp. 786. 63*s*.

THIS is the catalogue of the books illustrating the history of medicine and science collected, arranged, and annotated by Sir William Osler, and bequeathed by him to McGill University, Montreal. It is a vast volume of 786 quarto pages and shows Osler's catholicity. In the bequest to McGill we see the design of the testator to make the library possess a definite educational purpose, and this it does and much more also with its assistance. The plan of the catalogue was foreshadowed in 1911 and the work occupied Osler's few leisure moments throughout the intervening period until his death in 1919. Its preparation helped in some measure to mitigate the anxiety which the war brought him, an anxiety so sadly justified in the event, and at the time of his death the general outline had been sketched. It has fallen to Mr. W. W. Francis, the librarian of the Osler Library, Mr. R. H. Hill of the Bodleian Library, and Mr. Archibald Malloch, librarian of the New York Academy of Medicine, to complete the task by issuing the catalogue, their work being made possible by the whole-hearted coöperation of Lady Osler, who regrettably did not see the work finished.

The object of the index as laid down by Osler was to enable the hard-pressed student to learn first the evolution of knowledge in any subject and, secondly, the life and work of the men who made the original contributions; the general idea thus was to present in a comparatively small number of works the essential literature centring about the men of the first rank, arranged in chronological order. The Bibliotheca Osleriana, comprising about 7600 bound volumes, is grouped into eight sections as follows: (1) Prima: the beginnings (early civilisations), the medicine of the Greeks and the Arabians, the science and medicine of the Middle Ages, and the science and medicine with its scientific foundations and alliances of the sixteenth century down to the present day. (2) Secunda: the works of men which have some special interest but which are not so important as those in the Prima. (3) Litteraria: books dealing with the literary vocations and hobbies of medical men, with the relations of medicine and science to the world of letters, medical and philosophical poems, and "medicated" novels, or novels containing medical characters. (4) Historica and (5) Biographica: general histories of medicine and the stories of special medical movements or institutions. (6) Bibliographica: includes a vast collection of important catalogues. (7) Incunabula: a collection of more than 100 works printed before 1500. (8) Manuscripta: a collection in many languages comprising nearly 300 specimens, and including some of the collector's own writings.

It will be gathered that we have here a work of reference of the highest value both to individual students with many different wants, to those who want to correct or revise or criticise, and to all librarians. The advantage of sectional arrangement for reference is made available by a full and careful index of some 80 pages. It is unfortunate that the introductions which Osler intended to write as headings to the sections were never written, for his explanation to students how the Bibliotheca Osleriana was to be used would assuredly have made delightful reading. How to obtain and to pursue a knowledge of the history of science and of medicine would have been the very theme for his bright, learned, and logical pen, while the essays would certainly have constituted a wonderful commentary upon his own life—the life of the untiring and loving student.

While the library here catalogued constitutes the bulk of the literature brought together by Osler with a definite educational purpose, his bequests to the Medical Faculty of McGill did not exhaust his collection, for to Johns Hopkins University in Baltimore he left a collection of works, chiefly modern, on the arteries, blood, and tuberculosis, while to the Tudor and Stuart Club, at the same University, he left a collection of important editions of English works in memory of his only son Edward Revere Osler, who was killed in the war.

Recent Advances in Ophthalmology.

Second edition. By W. Stewart Duke-Elder, F.R.C.S., *Assistant Ophthalmic Surgeon, St. George's Hospital.* London: J. and A. Churchill. 1929. With 4 coloured plates and 110 text figures. Pp. 405. 12*s.* 6*d.*

A second edition of this work has been called for within 18 months of its original publication. The author has taken the opportunity to add new matter based on as many as 370 additional references and has still managed to keep the volume to a reasonable size. The new work on the eye here described can only be followed by those medical men whose knowledge is based on a fairly broad scientific foundation. In the first chapter the accounts of the structure of the atom and the nature of radiation take the reader at once into deep waters; in the last, a discussion of those aspects of Pavlov's experimental work which tend to prove that all cerebral action is reflex leaves him in a whirlpool. The new work detailed in the intermediate chapters is for the most part easier to grasp. The "chronaxie" of the retina—that is, its sensitiveness to electric stimulation of a certain duration—has been found to differ in different parts, the required duration being greater in the periphery than in the foveal region; this result is not surprising in view of the distribution of the rods and cones. In the chapter on embryology the important additions to our knowledge arising from the recent work of Miss Ida Mann have been incorporated.

From the clinical standpoint the chief interest of the book is found in Chapters IV., V., and VI. Chapter IV. is devoted to the newer methods of diagnosis—the slit lamp, ophthalmoscopy with red free light, and the examination of the angle of the anterior chamber by the gonioscope, and Chapter V. with the vascular circulation, the nature of the intra-ocular fluids, and the intra-ocular pressure. Much attention is devoted to the origin and nature of the vitreous. Its chemical composition is practically identical with that of the aqueous, with the addition of two constituents which, absorbing water and swelling up in solution, give rise to increased viscosity, elasticity, and a certain amount of solidity. A substance in this state is called by physicists a "gel"; it is structureless except to the ultra-microscope. In Chapter VI. the three diseases discussed are retinitis, glaucoma, and cataract. The problems connected with glaucoma do not appear to have advanced much nearer to a final solution. Mr. Duke-Elder appears to regard it as a disease in which increase of intra-ocular pressure is not necessarily the essential symptom. He says on p. 206:—

> "A series of cases like those reported by Pickard (1926), wherein a cupping of the disc resembling cavernous optic atrophy was accompanied by symptoms akin to glaucoma without detectable rise in the intra-ocular pressure, is difficult to explain on orthodox lines. Experimental evidence also seems to suggest that the formation and development of scotomata are not entirely dependent on pressure, but in some cases, at least, are due to changes in the fluid traffic of the retina; and clinically the progress of the symptoms does not run by any means parallel with the tension and frequently continues after its efficient relief."

This is hard doctrine for those who look upon glaucoma and raised intra-ocular tension as synonymous terms. We do not get much practical guidance with regard to non-operative methods of treating glaucoma. The action of adrenalin on the eye is to cause contraction of the arterioles, but to render the capillaries more permeable. An initial lowering of tension is followed by a slight rise. Hamburger's glaucosan, which tends to lower the tension but dilates the pupil, is only suitable for secondary glaucoma. In clinical work we have little justification for experimenting, since Mr. Duke-Elder finds both glaucosan and histamine unreliable drugs. The new method of intravenous injection of salt solution is mentioned, but only as a measure preliminary to operation. A chapter on general methods of treatment sets out the views of the author, founded on his own work at the Moorfields light clinic. In the final chapter on neurology, new matter concerning the pupillary paths and the oculo-motor system will be found. To the index of subjects an index of authors has now been added.

The activities of ophthalmologists seem to be extending rapidly just now, and Mr. Duke-Elder is keeping pace with them with great skill and judgment.

Electrotherapy.

The Principles of Electrotherapy and their Practical Application. Second edition. By W. J. Turrell, M.A., D.M., B.Ch. Oxf., D.M.R.E. Cantab., Consulting Physician, Oxford County and City Mental Hospital; Physician in charge of the Physiotherapy Department, Radcliffe Infirmary, Oxford. *London: Humphrey Milford, Oxford* University Press. 1929. Pp. 413. 10*s.*

Dr. Turrell's book is based upon a large practical experience of the diseases and complaints which can be cured or alleviated by electrotherapy. It is divided into six parts. An interesting historical chapter is followed by one on the therapeutic action of current electricity. The chief forms of the electrical current used in medicine are here outlined. A nice discrimination is shown by the author in describing the responses of the individual to currents of high and of low frequency, and of the currents which can be derived from the static machine. The therapeutic action of radiant energy is then considered; Dr. Turrell himself makes great use of the tungsten arc in hospital practice. Electrical Accidents and Electro-Diagnosis are discussed, and finally the application and mode of action of electricity in certain diseased conditions are outlined. This section takes up nearly 150 pages and should be of service to those who, having acquired some knowledge of the mode of action of the various currents, seek to apply them to patients.

Dr. Turrell has a long record of clinical experience, and has turned it to account in the application of electrical currents to damaged tissues or pathological conditions of widely different types.

UROLOGICAL ROENTGENOLOGY.

By HUGH H. YOUNG, M.D., Clinical Professor of Urology, Johns Hopkins University; Director, James Buchanan Blade Urological Institute; and CHAS. A. WATERS, Instructor in Clinical Roentgenology, Johns Hopkins University; Assistant Visiting Roentgenologist, Johns Hopkins Hospital. New York: Paul B. Hoeber. Pp. 499. $20.

THIS monograph is No. 7 of a series issued in America under the title of the Annals of Roentgenology. It is produced primarily for the use of radiologists though it contains material worthy of close study by urologists. Its main value lies in 518 figures, the majority being reproductions of actual radiograms of various conditions of urological interest. Taken for the most part from the service of the Blade Urological Institute and the Johns Hopkins University, these reflect the magnitude of the clinical area served by this institute and the ability of its director to make full use of the copious material. The radiograms—many of which are pyelograms, cystograms, and vesiculograms—cover every imaginable urinary condition and form a valuable collection for reference. Case-histories give a clue to the interpretation of the figures, though special points illustrated by individual radiograms should in some places have been more precisely indicated. Where radiograms are not supplied the text, which except in the first chapter is slender, is elucidated by beautiful drawings by Mr. Wm. P. Didusch. This first chapter, entitled Combined Roentgenological and Urological Study, is rigidly confined to the discussion of these aspects of technique which are common ground to both specialties—opaque media, the position of the patient for pyelography, perirenal insufflation, and so forth. Elsewhere the text consists of urological smatterings which are not sufficiently recondite to be valuable to the urologist and are of questionable importance from the radiologist's point of view. The authors have supplied them deliberately, however, holding that an intimate knowledge of the problem at issue on the part of the radiologist is essential to the success of the combined effort to solve it.

The book is beautifully though expensively produced. It represents faithfully the present stage in development of a youthful subject whose growth has been rapid and promises to continue so. The object of Dr. J. T. Case, the editor of the series, to supply a diagnostic guide rich in the fruit of experience of leading authorities in special fields has certainly been achieved in this volume.

PHYSICAL DIAGNOSIS.

Second edition. By CHARLES PHILLIPS EMERSON, A.B., M.D., Professor of Medicine, Indiana University School of Medicine. London: J. B. Lippincott Company. 1929. Pp. 553. 35s.

THIS book has been written because of the author's belief in the profound importance in medicine of the examination of the patient's body through the use of the unaided special senses, and his conviction that this will remain the primary and fundamental method of diagnosis. It is a rare change to have before us a book on diagnosis in which the use of microscopes or test-tubes is neither mentioned nor inferred. In the elucidation of disease, however, there can be no real subdivision, and a book rigidly confined to physical diagnosis is necessarily incomplete. In a work of over 500 pages on diagnosis in medicine we have a right to expect some material help in connexion with all the common medical states, but are occasionally disappointed in this one. For example, a search through the book for information on pernicious anæmia reveals only three references to this malady—the condition of the tongue, the colour of the skin, and the occasional enlargement of the spleen—the description of the blood being outside the scope of the work. If we accept these limitations as imposed on the author by his title, we can enjoy the pleasant writing and excellent balance of the sections allotted to each disease. The first chapter opens with an interesting historical sketch of the great masters in medical diagnosis, while the second deals with general body characteristics, types and attitudes in disease. The pages devoted to the general body surface contains a comprehensive account of the various skin conditions. The physical signs of the chest are accurately described and assessed with the mature pen judgment of an expert. References to recent contributions to literature are almost entirely confined to American publications. The photographs, the work of the Indiana University Department of Illustrations, are worthy of high praise.

OUTLINES OF DENTAL SCIENCE.

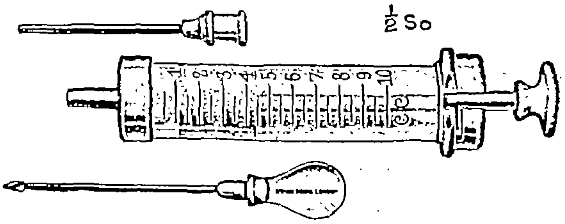
Dental Histology. By A. LIVINGSTON, M.D.S., M.B., Ch.B., L.D.S., Director of Dental Studies and Sub-Dean, King's College Hospital Dental School. Edinburgh: E. and S. Livingstone. 1929. Pp. 143. 7s. 6d.

THIS volume, which is one of a series of small books intended to cover the whole field of dentistry, is devoted to the histology of the dental tissues. It is clearly written and within the compass of 147 pages manages to convey a considerable amount of information. For revision purposes the student may find it useful, though used by itself it is scarcely full enough to satisfy examination requirements. The last chapter is devoted to microscopical methods and might with advantage have been more detailed. Should further editions be called for we would suggest that the meagre chapters on the structure of the tongue, oral mucosa, salivary and lymphatic glands might well be deleted and replaced by a more comprehensive description of histological methods with some account of the optical principles of the microscope. The illustrations are not numerous enough to be of real use.

New Inventions.

AN IMPROVED TROCAR AND CANNULA.

IN the aspiration of small abscesses, particularly in children, it is important to be able to carry this out as expeditiously as possible and with the minimum amount of inconvenience to the patient. The following are the outstanding points in the trocar and cannula here illustrated. (1) Comparatively short distance between point of trocar and end of cannula. (2) Close-fitting of end of cannula to trocar, which is narrowed for the purpose, thus enabling the cannula to slip easily into the opening made in the skin. (3) Convenient length and bore of cannula. The trocar is 2 in. long, No. 6 French catheter gauge, and is used with a 10 c.cm. metal and glass syringe.



The apparatus has been made for me by Messrs. Down Bros., Ltd., St. Thomas's-street, London, S.E.

GEORGE JESSEL, M.D. Oxf., D.P.H. Manch.

THE LANCET.

LONDON: SATURDAY, JULY 6, 1929.

PROBLEMS OF EPILEPSY.

There are at least two recognisable types of unsolved problem, the simple and the complex. In a simple, which is not synonymous with an easy, problem the task before the investigator is a well-defined one, for example the extraction of the active principle of a gland or the isolation of the infective agent responsible for a disease. The discoveries that rewarded the patience of Ehrlich, Ross, and Banting were solutions of such well-defined problems. On the other hand, there are diseases which at present defy explanation by their very complexity, and the two outstanding examples of these are cancer and epilepsy. The investigator of these baffling problems has no determined starting-point. Like a wanderer in a maze he is compelled to take one turning after another, following the path to which personal predilection invites him without any guarantee that it leads in the right direction, or even that it is not a blind alley. It is characteristic of our state of ignorance that the very use of the term "epilepsy" should be of problematic value. Many writers refuse to employ it except for a symptom evoked by a number of pathological states, and they speak therefore of the "epilepsies."

Good will come from an emphasis upon the variety of lesions of which a convulsion may be evidence. But the existence of comparatively gross causes for epilepsy in some cases does not justify the assumption that such are its only causes. Actually there is evidence for the existence of a constitutional ætiological factor even sometimes when a focal lesion is also present. The oft-quoted incidence of epilepsy in about 5 per cent. of cases of gunshot wound of the head in the late war, and the constancy of this rate in all combatant countries, appear to point to a predisposition to convulsions latent in these individuals; there seems no other adequate explanation for the fact that a family history of epilepsy is obtainable from some 30 per cent. of epileptics and is not uncommonly present in patients with an organic "cause" for their convulsions, such as a head injury. If a "constitutional" basis exists in at least a proportion of epileptics it is natural to inquire whether the epileptic habitus is one of its manifestations. The practitioner with experience of epileptics soon learns to recognise that they often exhibit a characteristic facies, apart, of course, from such accidents as scars and a bromide rash. So typical is the appearance of many epileptics that it is often possible to make a correct diagnosis at sight before the history has been given. We have at present no means of deciding whether the epileptic facies is the result of the fits or the expression of an underlying diathesis. Equally uncertain is the relationship between mental deterioration and epilepsy. It was at one time believed that the mental degeneration of the epileptic was largely, if not entirely, the result of the large quantities of sedative and depressant drugs which fell to his lot. This is almost certainly untrue, for the mental condition of most epileptics is improved by anticonvulsant drugs, and it is a striking fact that they do not as a rule experience the depressant effects of bromide and luminal to the same extent as normal persons. Sedatives appear to fulfil a physiological need in epileptics. It does not seem, however, that any direct relationship exists between convulsions and mental deterioration, for every clinician is familiar with epileptics who deteriorate little if at all in spite of frequent fits, while others, perhaps less frequently and less severely convulsed, nevertheless become progressively demented. Is the mental deterioration of the epileptic possibly also an expression of a constitutional defect, of which degeneracy and convulsions are independently variable manifestations?

The conception of an epileptic diathesis involves the view that there exist potential epileptics who lack the precipitating factor, the trigger which fires the charge. Such must have been the previous condition, on this hypothesis, of the 5 per cent. of wounded who only became epileptic following their injuries. The hypothesis of a constitutional abnormality underlying some forms of epilepsy is the incentive, implicit if not explicit, of most metabolic investigations into epilepsy. If epileptics possess no common metabolic abnormality such researches are doomed from the outset to disappointment. Such has indeed been the outcome of many painstaking labours in the past. A long list might be made of metabolic functions in epileptics which have been conclusively shown to be normal. Even reported abnormalities have hitherto found no general acceptance. Other observers have failed to confirm the alkalosis reported by Bigwood, or the "ammonia dysregulation" upon which Bisgaard and Norvig lay stress. It is, however, possible that a new and interesting chapter has been opened by the recent researches into the behaviour of the blood cholesterol in epilepsy. De Crinis and Pezzali first observed abnormalities in the blood cholesterol level in epileptics, and Popéa and Vicol drew attention to the association of a low blood cholesterol and disappearance of the lipoid of the suprarenal cortex in status epilepticus. Robinson, Brain, and Kay reported in our own columns[1] that the average blood cholesterol was lower in epileptics than in controls, and described 11 series of determinations, 10 of which showed a fall in the blood cholesterol level preceding a fit. We publish this week a communication reporting a further investigation of this question by Dr. Gosden, Dr. Tylor Fox, and Dr. Russell Brain. Using the method of serial determinations of the blood cholesterol at frequent intervals, these workers have confirmed the observations of Robinson, Brain, and Kay and demonstrated not only a depression of the blood cholesterol level during status and serial epilepsy, but its instability in association with isolated fits, and in four further instances a fall preceding an attack. Dr. Gosden, Dr. Fox, and Dr. Brain do not commit themselves to any theoretical explanation of these phenomena and are careful not to attribute any causative relationships between disturbances in the blood cholesterol level and the occurrence of convulsions. We know so little at present concerning the metabolism of cholesterol that these observations cannot be said to throw any direct light upon the cause of epilepsy. They do, however, appear to indicate the existence of a metabolic abnormality in epileptics and to suggest lines of research.

A definite fact concerning cholesterol which has long been familiar is its intimate relationship with the liver. It is secreted in the bile, being presumably by the liver from the blood stream. These tions upon the blood cholesterol in epilepsy re assume an added significance in the light investigation of the lævulose tolerance test optics reported by Dr. GOSDEN and Dr. TYLOR n this journal last week. These workers have only a small number of observations to record, they are of unusual interest. In several severe of epilepsy the lævulose tolerance tests yielded ts hitherto associated with extensive destructive ns of the liver. Less severe cases showed an airment of lævulose tolerance of less degree. 's to be hoped that further investigations will made on these lines. It is common experience t considerable destruction of the liver may take ce without any detectable abnormality in the vulose tolerance test. The findings of Dr. GOSDEN and r. FOX point therefore to a functional liver deficiency f extreme severity occurring in epileptics, though here is nothing in their observations to indicate the hysiological relationship of this disturbance to the ttacks. A number of years ago MYERSON observed in a small series of autopsies upon epileptics that the weight of the liver was subnormal in a large proportion of cases. This observation has since been confirmed by THOM, and more recently by PATTERSON and WEINGROW. Here there are hints, both anatomical and physiological, that constitutional abnormalities may be present in epileptics, and there are sufficient indications to encourage energetic research into their hepatic functions. Those who regard epilepsy as merely a symptom must admit that if they are right there is little hope of alleviating the complaint on a large scale. Those who seek an epileptic diathesis may encourage themselves with the knowledge that, if such could be discovered, an important advance would have been made towards a cure.

---

[1] The Lancet, 1927, ii., 325.

It is one of the fascinations of epilepsy as a subject of research that it presents so many aspects which, though necessarily related, are nevertheless to a large extent capable of independent consideration. It is not improbable that a metabolic abnormality might be discovered and relieved in epilepsy without its convulsant effects being understood, a situation similar to that which has arisen in the treatment of pernicious anæmia. Hence there is unlimited scope for those whose interest leads them to seek the physiological nature of a convulsion or the precipitating factors which lead to the onset of a fit. The belief that cerebral vasoconstriction plays such a rôle has long been held, though perhaps never on grounds which could entirely withstand criticism. The relationship between the concomitant vasomotor changes and the attack well illustrates the complexity of the problems of epilepsy. Blanching of the cerebral cortex at the beginning of a fit has been observed on several occasions by surgeons, but at the time when stress was laid upon this observation it was not fully understood how profoundly the opening of the skull alters the normal conditions of cerebral circulation. Moreover, even if cerebral vasoconstriction does occur at the beginning of a fit, parallel to the generalised cutaneous pallor, this is far from a proof that it causes the attack. Such vasomotor changes may merely indicate the participation of the sympathetic nervous system in the neural discharge which constitutes the fit. However, even if the vasomotor origin of the convulsion should prove to be mistaken, it will have shown once again the value of error, for this theory has led to the illuminating researches of COBB and FORBES which have gone far to establish the existence of vasomotor nerves to the cerebral blood-vessels. Those who look elsewhere than in the circulatory system for the genesis of the fit will probably expect to find it in a disordered metabolic state of the cerebral neurones, which expresses itself in a tendency to an uncontrolled discharge of energy. Here we reach the obscure realms of excitation and inhibition which neurology is now only beginning to explore. Already, however, we can recognise possible relationships between sleep, trance, narcolepsy, catalepsy, and epilepsy. The long familiar influence of waking and sleeping upon epileptic fits has recently been analysed in this journal by Dr. MARY LANGDON-DOWN and Dr. BRAIN, who have demonstrated that some epileptics react to sleep in a manner diametrically opposite to others, and suggest that this difference may lie in their response to the inhibitory influence which in PAVLOV'S view is the essential nature of sleep. From such considerations, at present necessarily speculative, it is but a step to the excitations and inhibitions which find expression in thought, feeling, and action, the influence of which upon epileptics is as profound as any metabolic or physiological changes. When fear may precipitate a fit and interest or effort avert one it is clear that psychology may have light to throw upon the nature of epilepsy.

In conclusion two facts may justifiably be emphasised. There was never less cause for pessimism as to the outcome of research upon epilepsy. But there was never a subject of research which so much necessitated a broad outlook in its investigation, and the closest possible collaboration between the biochemist, the physiologist, and the clinician.

COSMETIC SURGERY.

AWHILE ago we published a lively account of the award of 200,000 francs damages against an eminent Paris surgeon in a French court of law.[1] A patient, contemplating matrimony, was concerned as to the lack of symmetry of her legs. She consulted a surgeon who consented to perform an operation, reducing the right leg; owing, however, to difficulties of circulation, gangrene supervened and amputation became necessary. This substantial award of damages being regarded as a serious threat to certain aspects of French surgery, Dr. DARTIGUES, a past president both of the Société des Chirurgiens de Paris and of the Société des Médecins de Paris, brought the matter before the General Council of the Association Générale des Médecins de France in a vigorous protest. From this address it seems that the judge took the view that this particular operation was not necessitated by therapeutic considerations, that French law is not prepared to recognise certain operations of a merely "facultative" nature, and that the patient was deemed to be so strongly obsessed by her physical deformity that she was incapable of forming an independent judgment, or giving a legal consent to the operation which was, in fact, performed.

Without more exact knowledge of the grounds of the judicial decision (which, moreover, may be subject to appeal), it is difficult to comment on it. In England it would presumably be a mere issue of negligence. Cosmetic surgery has not yet occupied our judges' time, though they are familiar with claims for damages when dermatitis is alleged to have supervened after the application of hair-dyes. A woman's desire to look her best, and the disadvantage which age or disfigurement impose upon her matrimonial chances, are matters of which English judges and juries would undoubtedly take notice. In breach of promise actions juries are invited to assess the damage caused to a woman through the default of a fiancé to whom she was engaged during several years of her most marriageable age. In cases arising out of traffic accidents, injuries such as facial scars would similarly be regarded as a particular reason for liberality of compensation, and, if some physical disability were caused which modern surgery could ameliorate or remove, the cost of such further operation would no doubt be put forward as special damage due to the original accident. The criminal aspects of cosmetic surgery are even more speculative. As the law recognises the profession of surgery, it must admit the right of the patient to consent to the infliction of any bodily injury in the nature of a surgical operation, though such consent does not discharge the surgeon from the usual duty to exercise due care. STEPHEN, in his *Digest of the Criminal Law*, says further, that everyone has a right to consent to the infliction upon himself of bodily harm not amounting to maiming. He goes on to say that no one has a right to consent to the infliction upon himself of death, or of an injury likely to cause death, or of bodily harm amounting to maiming, *for any purpose injurious to the public*. He explains that he inserts the italicised words because it would be absurd to say that, if a dentist pulls out a patient's front tooth on the ground that the tooth, though not diseased, is unsightly, the patient and the dentist both commit a misdemeanour. For a clearer view of the English law we must wait till some definite case of the kind comes before the courts.

---

[1] THE LANCET, March 16th, p. 576.

Dr. DARTIGUES, in his address, asked what was the proper sphere of "plastic" and "æsthetic" surgery, the epithets being in his opinion synonymous. Nobody doubts the propriety of using surgery as a corrective of congenital malformation or variation from the normal human type. It is equally applicable to remedy injuries due to accident or, as the last fifteen years have shown, injuries due to war. Coming down to the removal of facial lines or wrinkles and similar supposed blemishes upon feminine beauty, Dr. DARTIGUES has no hesitation in offering the resources of surgery here also. Æsthetic surgery in his definition is the sum of all operations of a plastic character intended to remedy natural or acquired defects in the human morphology which prejudice the personal and social value of the individual. He would agree, no doubt, that it is for the surgeon and not the patient to decide upon the propriety of the operation. If the beauty parlour movement develops a type of unqualified practitioner who, for a large fee, will exploit some fashionable operation for the mere removal of fancied blemishes, the law could hardly ignore the adverse consequences of risks thus run. Not long ago Prof. ARCHIBALD YOUNG, writing in our columns on the injection treatment of varicose veins, stated that he had several times been asked by quite young girls to apply the treatment to some odd superficial vein which caused no trouble whatever. Operation for mere beautification may be among the things which are lawful and yet not necessarily among those which are expedient.

DIPHTHERIA PROPHYLACTIC.

SINCE active immunisation against diphtheria became an everyday practice much attention has been devoted by laboratory workers to the subject of the antigen. In America this was originally an underneutralised mixture of toxin-antitoxin which was later replaced by a mixture in which the slight excess of toxin was further reduced, and the latter until quite recently has been extensively employed throughout the United States. Certain objections have, however, been raised from time to time to toxin-antitoxin mixtures and in this country they were superseded several years ago by toxoid-antitoxin. Toxoid, described by G. RAMON in 1923 and named "anatoxine" by him, is a modification of diphtheria toxin brought about by the addition of formaldehyde and exposure to a temperature of 38° to 40° C. for from four to six weeks. The process deprives the toxin of its toxicity but leaves the preparation in possession of well-marked antigenic properties, and it is in general use in serum laboratories for the preparation of diphtheria antitoxin. In this country toxoid alone has never replaced toxoid-antitoxin for immunisation of humans, although the procedures involved in its manufacture in the laboratory are simpler. As well as being a very efficient immunising agent, it has the further advantage that, since it contains no antitoxin fraction, immunised individuals are not sensitised to horse serum, a factor of some importance in these days when serotherapy is so widely employed for various conditions. It has, however, been given an extensive trial in France and Canada and now[1] we are indebted to Drs. GEORGE and GLADYS DICK for information on the comparative values of the immunity induced by toxin-antitoxin mixture and toxoid.

Two groups of susceptible individuals each numbering 100, mostly student nurses, have been immunised with each type of prophylactic to the point of being Schick negative. In the toxin-antitoxin group a preliminary injection of 0·5 c.cm. followed by four injections of 1 c.cm. at weekly intervals was given, whilst an interval of three months or longer was allowed to elapse before the reapplication of the Schick test. The toxoid group received three doses of 0·5, 1·0, and 1·5 c.cm., a two weekly period intervening between the injections, and retests were made not sooner than six weeks after immunisation was completed. It was found that in the toxoid group 91 per cent. of the total number, and excluding children 93·3 per cent., gave a negative Schick test, whilst in the toxin-antitoxin group 82 per cent. became negative reactors. Thus it appears that toxoid is a better immunising agent than toxin-antitoxin. The incidence of reactions has been carefully noted in the toxoid group, when 31·0 per cent. showed small local reactions, 0 per cent. large local reactions, 28·5 per cent. slight general reactions, and 6·3 per cent. moderate to severe local reactions. These observations are of considerable value, for the reason that toxoid has made little headway in this country, in spite of the advantages noted above, is probably because one or two workers have reported severe reactions following its use. The suggestion has been made that the reactions are the result of sensitiveness to some product of bacterial metabolism in the antigen, whilst others are of the opinion that the sensitiveness is towards some protein constituent of the medium in which the organism was originally grown. The Drs. DICK show, by an analysis of the nine severe general reactions represented by the 6·3 per cent. mentioned above, that when the original Schick test was performed five were marked and one was a moderate pseudo-reactor, whilst two had previous attacks of diphtheria. Whatever the real explanation of these reactions, the practical point that emerges is that they can be avoided or mitigated by commencing the immunisation of pseudo-reactors or persons in whom diphtheria has formerly occurred with small doses such as 0·1 or 0·25 c.cm. In view of to psycho-analysis (in the strict sense) a weight to which no other system of mental analysis is prima facie entitled. Psycho-analysis, both as a theory of psychology and as a therapeutic technique (the word covers both senses), deserves to be treated with the greatest respect. And though the Committee are non-committal about the most important issues, they pronounce quite definitely on some of the criticisms to which psycho-analysis has been subjected. They reply to the suggestion that "psycho-analysis applied as medical treatment may cause insanity in the patient" with the categorical "No proof of this charge has been discovered by the Committee." They refute the suggestions that psycho-analysis ignores the relation of the body to the mind, that it is materialistic and that it is inordinately expensive. They are satisfied that it is impossible to make a verbal record of an actual psycho-analysis in order to present it to a sceptical public. On all these points the contentions of the psycho-analysts are upheld.

---

[1] Jour. Amer. Med. Assoc., June 8th, 1929.

The summary of "modern psycho-analytical methods and teaching," which the Committee "has reason to believe" to be "correct as far as it goes," lays great stress on the resistances which prevent the emergence into consciousness of parts of the unconscious mind, and describes the aim of a psycho-analysis as the overcoming of these resistances. In the replies to criticisms of psycho-analysis, which replies (provided by the President of the British Psycho-Analytical Society) and criticisms the Committee "leaves to the judgment of the reader," the element of resistance in the attacks of critics is emphasised. Thus the Committee, while declining to commit itself upon the truth or value of Freudian psycho-analysis, may fairly be said both to treat it with respect and to recognise that the charge of emotional prejudice which psycho-analysts make against their critics may have some foundation.

NEOSALVARSAN AS A PULMONARY ANTISEPTIC.

INTEREST in chronic lung diseases and the applications of surgery to their treatment has been greatly stimulated by Dr. R. A. Young's masterly review of this subject in his Lumleian Lectures delivered in London in March of this year.[1] Of such conditions there are few that demand greater care and judgment on the part of the physician than that of empyema, particularly when streptococcal in origin, and of chronic bronchiectasis. In the former there is general agreement that too early operation may and in fact usually does lead to that troublesome condition, chronic empyema. This result of treatment by open operation has led many workers to treat such cases by continuous aspiration, with or without irrigation of the cavity with some form of antiseptic solution. That most usually employed has been Dakin's solution—neutral 0·5 per cent. solution of sodium hypochlorite—though others have also found their advocates. Recently Dr Hans Edel[2] has recorded a few cases which he has treated with intrapleural injection of neosalvarsan. His treatment has been to aspirate the pus through a needle of moderate size, using the same needle to inject at once a solution of neosalvarsan. Edel has found that the pleura is able to withstand large doses of this solution without undue reaction; thus his usual initial dose has been 0·45 g. dissolved in 10 c.cm. distilled water, which is gradually increased up to 0·6 g. according to the general reaction and the degree of refilling of the empyema. The surprising tolerance shown by the pleura to such high dosage suggests to Edel that considerable local thrombosis occurs round the site of the injection. It is, of course, well known that neosalvarsan even in far weaker solutions is a powerful antiseptic, especially against streptococci, and it is natural that the attempt should be made to utilise it at the site of infection instead of in the blood stream alone. Edel has gone further and has injected solutions of similar strength (from 0·15 to 0·6 g. dissolved in 10 c.cm. of water) into the bronchial tree in cases of bronchiectasis. His method has been similar to that used for the introduction of lipiodol into the lung, namely, cocainisation of the trachea and direct injection through a laryngeal catheter. In the few patients he has so far treated Edel reports considerable success, the total quantity of neosalvarsan used being in one case as much as 5·25 g. Another patient suffering from right-sided pulmonary gangrene and empyema received in all 0·9 g. into the pleura and 2·7 g. into the lung, a total of 3·6 g. The patient became afebrile two days after the first injection and in 12 days the empyema had disappeared, "cure" resulting in seven weeks, though the X ray still showed some thickening of the pleura. The local application of arsenical bactericides in pulmonary conditions is a method to be watched with interest, although clinicians may hesitate to copy the high dosage employed by Dr. Edel until further results have been reported.

LOSS OF APPETITE IN CHILDHOOD.

THE literature of anorexia in children is voluminous and the underlying causes sponsored by individual writers innumerable. Some fresh light has, however, been recently thrown on the subject by a stimulating article from the pen of Dr. Joseph Garland,[1] who attributes the trouble essentially to a failure of management in the earliest weeks of life and confirmed in childhood by improper training and discipline. Thus he suggests that the initial loss of weight that occurs before the establishment of complete lactation is in itself an advantage to the baby, as during these first few days the sensation of appetite has time to develop, a sensation that the baby is never likely to lose subsequently. Once breast feeding has been established a transient loss of appetite is a usual occurrence during acute febrile disturbances, and may in fact be interpreted as a protective mechanism since the gastro-intestinal tract, under the circumstances, is not commonly prepared for the reception and utilisation of food. It is frequently found that the mother's greatest source of anxiety during the illness of a child is the failure to take nutriment, and it may require considerable patience to explain the situation to her. In many cases it should be realised that the appetite difficulty is not a real one at all, but exists only in the fertile imagination of the over-anxious parent. This is often the case with infants at the breast who take their feeds so rapidly that the mother becomes obsessed with the idea that little or no milk has been taken; weighing the baby before and after feeds will generally banish this illusion. Sometimes an artificially fed infant will fail to finish its carefully calculated allowance but continues to gain at a satisfactory rate. This baby does not require as much food as another infant of the same age and weight. One of the greatest boons that could be granted mankind would be an appreciation of the fact that all human beings are individuals with varying digestive capacities with varying temperatures, levels of activity, and caloric requirements.

The period of starting new foods, which includes very definitely the weaning period, presents often the first great obstacle to the continuation of a normal appetite. Habits of feeding have become firmly fixed, and infants, like their elders, resent change. Where such difficulties arise it is absolutely essential to ensure firmness in management on the part of mother and nurse, even if this entails two or three days' misery for all concerned. The physical causes of anorexia, admittedly much less frequent than the psychic, are usually quite apparent in themselves, although frequently it is necessary to disabuse a parent or nurse of the idea that a physical cause exists where in reality a search reveals none, and where it is obvious that the true fault lies elsewhere. It should be mentioned that over-feeding with milk is a natural mistake which a zealous mother frequently makes without realising the fact that milk, particularly with a child over a year old, is a very filling and appetite-destroying food; in no case should a child be given more than a pint a day. The importance of fatigue upon appetite cannot be over-estimated, and is especially apparent as a result of the intense "urbanisation" to which the modern child is subjected. Even in play the possibility of fatigue is present and disaster frequently awaits the highly strung child, who forces himself to follow the leadership of older and stronger children. It can readily be seen how difficult it is to analyse the cause of anorexia in a given case, and how much reliance must be placed on a detailed history of the home life and surroundings. While the shortcomings and difficulties of the particular case are being poured out by the despairing parents, the child himself is delighting in the fact that he will not eat a morsel of vegetables and that only with the utmost coaxing can he be persuaded to take any milk pudding. What a little price, he may well feel, is the loss of a few meals for such a sense of importance? Many children will not eat because that is what is expected of them, but who can blame them when they hear their parents discussing their own food idiosyncrasies at every meal?

---

[1] Garland, J.: New Eng. Jour. of Med., 1929, cc., 1135.

The clinical picture is known to all but the correct lines of treatment are difficult to carry out. Dr. Garland indicates some of them. A thorough explanation of the situation should be given to both parents in the absence of the child and they should be exhorted to ignore all symptoms and never discuss details of the patient's management in front of him. It should be almost unnecessary to remark that heaping a child's plate with all that he is supposed to eat for the entire meal is to discourage him from the start. In the same way the meal should be attractively served on a tray, which is removed without comment at the end of a specified time and under no circumstances should he be urged or bribed to eat. In many instances it will be advisable to separate the child entirely for a time from his home surroundings and place him among other children where he will have companionship and judicious management. The whole subject is admittedly difficult and indicates the necessity for adequate instruction of parents in mothercraft, so that the child's habits can be trained on correct lines from the beginning.

A MODEL MEDICAL MUSEUM.

THE museums of most of our medical schools contain magnificent accumulations of admirable preparations. But as instruments of education they suffer from three substantial defects: (1) the rare and curious is much too prominent; (2) their arrangement fosters the notion that pathology has to do with states rather than processes; (3) the labelling and accessory illustrations are wholly inadequate, chiefly, we fancy, because the things in bottles are primarily looked upon as the objects in guessing competitions in examinations. The ideal that the exhibits in a museum should be illustrations of a text-book of their subject and should be amply supplemented by reading matter, pictures, diagrams, and so forth, has for a long time guided the arrangement of zoological and antiquarian collections. Those who wish to see the same plan applied to medicine should visit the museum at 33, Gordon-street provided by the generosity of Mr. Wellcome and presided over by Dr. Daukes. If they have not been before, they will be surprised, and we believe delighted. In a well-illustrated volume[1] (which may be had gratis from the museum by those interested) Dr. Daukes has explained the theory and practice of what he has done in a very interesting and informative way. We hope he will gain many converts to his methods, and those who are not prepared to go with him all the way will find many useful hints about museum technique.

RADIUM TECHNIQUE.

A POST-GRADUATE course on radium therapy will be held at St. Bartholomew's Medical College, London, from Monday, Sept. 30th, to Thursday, Oct. 3rd. Entry to the course, which will be of an introductory character, is limited to about 30 men, those who are likely to work with radium being preferred. Lectures will be given on the physical properties of radium and radon by Prof. F. L. Hopwood, on the biological aspect of radium by Dr. R. G. Canti, on its surface application by Dr. N. S. Finzi, and on its use in combination with deep X rays by Dr. W. M. Levitt. The applications of radium to the treatment of special regions will be made by Sir Charles Gordon-Watson for the rectum, Prof. G. E. Gask for the tongue and mouth, Dr. Malcolm Donaldson for gynæcology, Mr. Douglas Harmer for the larynx and air passages, and Mr. Geoffrey Keynes for the breast. On each day there will be demonstrations in the out-patient department or in the wards, and on three of the days operations will be carried out by members of the staff, including, besides those already mentioned, Dr. J. D. Barris, Mr. F. A. Rose, and Mr. Bedford Russell. Application for admission to the course, which is something of a new departure, should be made to the Dean of the Medical College. The terms may be seen in our advertisement columns.

One important side of radium technique is dealt with in our own columns this week by Dr. Joseph Muir of New York, who has made the subject peculiarly his own, for it was he who originated the use of the screened radon seed in the treatment of malignant growths. That the method opens up a promising line of work was admitted by Prof. Gask when addressing the British Empire Cancer Campaign a year ago.[2] Surrender of the use of radon is by no means a foregone conclusion even should a largely enhanced quantity of radium become accessible for general use in the near future, for increasing stress is being laid on the unwisdom of allowing radium element to leave the centres where it can be jealously guarded. Dr. Muir has for long championed the use of the glass tube containing radium emanation encased in a layer of platinum 0·3 to 0·4 mm. thick; although somewhat larger than the gold seed in common use in America, it has the advantage of being watertight and smooth, while it can be removed as soon as the treatment is concluded by means of the threads which are left in position. The unscreened or bare tube Dr. Muir regards as standing condemned owing to the zone of necrosis which invariably forms around it. In the œsophagus the dangers of tissue necrosis are great enough even with the screened tube, and sloughing in this position means a fistula into lung or trachea with rapidly fatal results; but even in complete stricture Dr. Muir claims to have restored the lumen of the œsophagus and to have so far relieved the patient as to permit him to resume ordinary diet and habits. In the uterus when the cervical canal is completely blocked by malignant tissue, he regards it as possible for a skilful operator to implant such screened seeds in the highly friable tissues without inflicting further trauma, and in this way so to clean up the malignant area as to render possible the more usual application of radium.

In prostatic cases the radon seed enables escape from the prolonged hospital stay which deters from other forms of treatment.

THE WELFARE OF THE DEAF.

ON Thursday next, July 11th, at 3.30 P.M., the National Institute of the Deaf will hold its fifth annual meeting at the Caxton Hall, Westminster, S.W., when Lord Charnwood, who will preside, will be supported by Sir Frank Benson, Mr. Somerville Hastings, M.P., and others who realise the importance to the community of promoting the interests of the deaf. There are some 40,000 persons in Great Britain who have been deaf from birth or very early life, and while it is incumbent upon the State to make proper provision for these unfortunate people who demand our utmost sympathy, the loss in personnel and money to the country from want of proper attention to this afflicted class is very great. The appointment by the Government of a Departmental Committee at an early date to investigate this question was advocated by the Duke of Montrose in vigorous terms at the last annual meeting of the Institute, while it is now 40 years since any Government Department has made inquiry along the needed lines. The industrial hardships caused by deafness and their grave social implications were emphasised at an important meeting of the Institute, which was held at the London Mansion House three years ago, when the Duchess of Atholl pleaded the cause of the deaf eloquently. Much has been done by the untiring efforts of the Institute, in spite of financial difficulty, but official help is needed for much remains to be done. The meeting at the Caxton Hall next Thursday will be open to the public, who are invited to lend their support.

MATERNITY AND CHILD WELFARE CONFERENCE.

WHAT bids fair to be a most successful meeting, promoted by the National Association for Prevention of Infant Mortality in conjunction with many other allied bodies, opened at Friends House, Euston-road, on Tuesday last. The Marchioness of Aberdeen and Temair, who presided at the inaugural session in the unavoidable absence of the Minister of Health (who is to deliver his Presidential address later in the week), referred to the world-wide interest now awakened in this subject and the recognised need for obtaining the full coöperation of the fathers in the movement. Lady Aberdeen laid great stress on the disastrous results to family life from the maternal morbidity and morbidity dating from childbirth, and also gave expression to the general rejoicing and relief at the recovery of H.M. The King from his recent illness. After wishing success to the deliberations of the delegates, who number nearly 1000 and include representatives of the overseas Dominions and more than 36 English-speaking countries, Lady Aberdeen presented the challenge shields and prizes to the successful competitors in the various competitions arranged under the auspices of the National Baby Week Council. The Imperial Challenge Shield, which was won last year by Benoni in the Transvaal, has been won for 1928–29 by Kalutara, Ceylon, and Dr. C. P. Williams, Medical Officer of Health for Ceylon, was in attendance to receive the Certificate of Merit on behalf of the Kalutara Baby Week Committee. The Maharaja of Burdwan presided in the afternoon, and the whole of the first day was devoted to the consideration of the welfare of the child between 1 and 5 years. The branches of the subject discussed included child guidance clinics, the State care of children, the prevention and cure of crippling, and the handicap of illegitimate children, whilst the psychological aspect of the problem was debated in the evening at the annual meeting of the Association of Infant Welfare and Maternity Centres. Among the other subjects for discussion at the conference are maternal morbidity, special V.D. clinics in connexion with maternity and child welfare held departments, and methods of preventing undue delay in the out-patient departments of hospitals.

THE Imperial Social Hygiene Congress will be held from July 8th to 12th at Livingstone Hall, Broadway, London, S.W. 1., Lord Linlithgow presiding. Invitations have been sent to the Governments, universities, and organisations concerned with social hygiene throughout the Empire, and 200 delegates are expected.

INDEX TO "THE LANCET," VOL. I., 1929.

THE Index and Title-page to Vol. I., 1929, which was completed with the issue of June 29th, is now in preparation. A copy will be sent gratis to subscribers on receipt of a post-card addressed to the Manager of THE LANCET, 1, Bedford-street, Strand, W.C. 2. Subscribers who have not already indicated their desire to receive Indexes regularly as published should do so now.

The Services.

ROYAL NAVAL MEDICAL SERVICE.

Surg. Capt. J. H. Fergusson to be Surg. Rear-Admiral.

The following appointments are notified: Surg. Lt.-Comdr. (D.) C. Williams to *Pembroke*. Surg. Lts. H. L. Duncan to *Carysfort*, T. A. Cochrane and J. Cassen to *Vivid*, W. P. E. McIntyre to *Effingham*, J. W. Nesbitt to *Cleopatra*, and E. B. Pollard to *Victory XI*.

ROYAL NAVAL VOLUNTEER RESERVE.

Surg. Sub.-Lt. D. M. Craig to be Surg. Lt.

Proby. Surg. Lt. A. H. Shelswell to be Surg. Lt.

The following appointments are notified: Surg. Lt.-Comdr. R. H. O. B. Robinson to *Victory*, for R.N. Hospital, Haslar. Surg. Lt. R. L. S. Stubbs to *Pembroke*, for R.N. Barracks.

ROYAL ARMY MEDICAL CORPS.

Capt. P. N. Creagh (late R.A.M.C., T.F.) to be Temp. Capt., and temporarily relinquishes the rank of Capt.

ARMY DENTAL CORPS.

Capt. A. F. Salsbury to be Maj.

TERRITORIAL ARMY.

Lt.-Col. H. F. Humphreys to be Bt. Col.

Maj. G. H. Stevenson (late R.A.M.C., Militia) to be Maj.

Capt. R. K. Nisbet relinquishes his commn.

Lt. D. O. Vaughan to be Capt.

Lt. E. S. Kirkhouse (late 3rd Bn. K.O.S.B.) to be Lt.

G. B. Matthews to be Lt.

Supernumerary for Service with O.T.C.—2nd Lt. G. B. Scholefield (late R.E.) to be Lt. supern. for serv. with Med. Unit, Univ. of Lond. Contgt., Sen. Div., O.T.C.

TERRITORIAL ARMY RESERVE OF OFFICERS.

Maj. C. B. Baxter, from Active List, to be Maj.

Lt. L. Gardiner (Army Dental Corps), from 6th Bn. E. Surrey R., to be Lt.

INDIAN MEDICAL SERVICE.

Capt. L. K. Ledger to be Maj.

Temp. Lt. Mir Saleem Mahmood relinquishes his temp. commn.

DEATHS IN THE SERVICES.

Lt.-Col. George Henderson, late I.M.S., who died at Inverness on June 23rd in his ninety-third year, was educated at Aberdeen University and graduated M.D. in 1868, obtaining the L.R.C.S.E. in the same year. In the following year he went to India and for some time served in the Indian Medical Department as civil assistant surgeon at Shahpur. In 1865–67 he became officiating professor of medicine and surgery at Lahore Medical College and afterwards superintendent of the Lahore Central Jail. Later he became officiating superintendent of the Botanical Gardens in Bengal and professor of botany in the University of Calcutta. Subsequently he was appointed civil surgeon at Gujranwala and also served at other stations in the Punjab. He retired in 1890. Lt.-Col. Henderson leaves a widow, two sons, and two daughters.

The Clinical Interpretation of Aids to Diagnosis.

A Series of Special Articles contributed by Invitation.

XXXVI. CHARTS OF FRACTIONAL TEST-MEALS.

PART I.*—NORMAL CURVES.

GASTRIC analysis is a less exact procedure than the majority of biochemical investigations, for not only do the stomach contents exhibit a greater normal variation in their chemical composition than do most substances recoverable from the body, but this variation is itself dependent on a series of factors which change in a given individual from hour to hour and from day to day.

The Variable Factors.

The more important of the variables concerned may be divided into: (*a*) extrinsic, and (*b*) intrinsic factors—and these may be further subdivided in the following manner:—

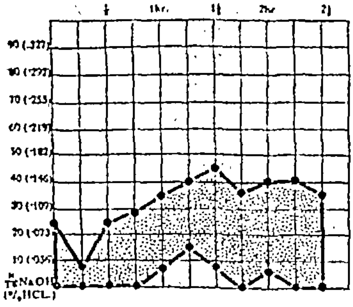
Extrinsic Factors.—(1) *The composition of the meal.* This will vary even when a fairly simple dietetic material, such as oatmeal gruel or toast and water, is selected in every case.

(2) *The Fasting Stomach Content.*—This varies considerably from case to case and even in the same individual from day to day.

Intrinsic Factors.—(1) The *stomach content* at any moment is a mixture of food, of secretion from the gastric glands, of secretion from the salivary glands, and of duodenal contents regurgitated through the pylorus. Not only do these factors vary from individual to individual, but in every individual there is some degree of daily personal variation.

(2) *Psychic factors* can be of great importance. Difficulties in swallowing the tube and apprehension after swallowing it will sometimes cause an inhibition of gastric secretion, and as the subject under investigation is almost invariably being examined for the first time, inhibition is a factor which must be taken into account.

FIG. 1.



The limits of normal curves for free HCl.

(3) *Errors in Sampling.*—The stomach contents are never homogeneous. Those recovered from the pyloric antrum are usually more acid than those at the cardiac end, and in addition it is obvious that in an actively secreting stomach the contents close to the mucosa will be the first to receive secretion. Experience in the withdrawal of samples for gastric analysis overcomes grave error from this cause in most cases, but it is clear from the foregoing paragraphs that inexperience in the practical side of collecting samples for gastric analysis is a more important potential source of error than is the possibility of inexpert chemical analysis of the samples themselves.

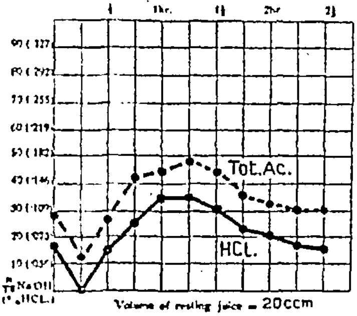
For these reasons, whenever an important decision rests on the interpretation of a fractional gastric analysis, the recovery of the samples should be confided to someone fully experienced in the procedure.

Collection of Samples.

If, however, the practitioner himself desires to collect the samples, it should be done according to the following technique, fuller details of which are available in current text-books.

The patient is allowed no food or drink after 9 o'clock on the night preceding the examination. At that hour it is well to give some charcoal biscuits or a glass of milk containing powdered charcoal, in order to provide a substance readily recognisable if a high degree of pyloric stenosis is present. On the morning of the examination, about 9 o'clock the patient swallows the tube and by means of a 20 c.cm. "Record" syringe the whole of the fasting stomach content is withdrawn, measured, and carefully preserved. If the total bulk is less than 10 c.cm., it is probable that the stomach had not been completely evacuated, and it is sometimes well to introduce one or two syringes full of warm water to assist in recovering the residual contents. In such cases it must, of course, be noted that the fluid withdrawn has been diluted by the water added.

FIG. 2.



The average normal curve for free HCl and total acidity.

The stomach being empty, the patient, with the tube in position, is given a pint of gruel made by boiling two tablespoonfuls of fine breakfast oatmeal in a quart of water until the total bulk has been reduced to one pint. The mixture is then strained and flavoured with salt, unless chloride estimations are to be made.

It is at that stage of the examination that the patient is most likely to experience discomfort or nausea, and, therefore, a light magazine or daily newspaper should be provided and the patient encouraged to read very attentively for at least ten minutes. At quarter-hourly intervals, after swallowing the meal, samples of 5–10 c.cm. are withdrawn by the syringe and preserved in test-tubes, labelled one-quarter, one-half, &c. Care should be taken to ensure that these samples are recovered from the stomach contents and not from the duodenum or some isolated loculus. This can be accomplished by noting that the tube is at the right depth and occasionally withdrawing it one or two inches, or getting the patient to swallow it deeper if its position has materially changed.

If the stomach appears to empty with undue rapidity, the tube should be moved about and aspiration attempted in different positions before it is assumed that the contents have all passed on. At the end of 2½ hours it is usual to empty the stomach completely and to make a note of the volume of the contents, a 10 c.cm. sample of which is [illegible] for analysis. The samples thus collected, [illegible] notes concerning the patient and the total volume of the fasting content and the final residuum, may be forwarded to a laboratory for analysis and will not undergo material chemical change during a period of fully 12 hours.

---

* Part II., on the interpretation of charts in patients showing high acidity, low acidity, and of charts suggestive of gastric carcinoma will follow next week.

Details of the Report.

A report of a fractional gastric analysis should supply information on the following points:—

(*a*) The volume and character of the fasting stomach content.

(*b*) The character of the samples recovered at intervals after the taking of the test-meal.

(*c*) The volume and character of the total stomach content at a sufficiently long time after the taking of the meal for it to be reasonably expected that the stomach will be nearly empty. Two and a half hours is usually the longest time over which the examination is continued, but in cases of pyloric obstruction the analyst sometimes continues to extract specimens for three hours or longer. In any case, the total volume of the stomach content at the end of the examination should be determined and recorded.

As in every laboratory procedure, it is wise to supply the analyst with brief details of the case and special points requiring particular investigation. Thus, in a case of suspected cancer of the stomach it will always help the analyst if he is informed of the provisional diagnosis, and he will in such circumstances apply particular attention to the investigation of the fasting stomach content and may make special search for occult blood, lactic acid, or the presence of abnormal cells in the samples investigated. Or, again, in cases of suspected pernicious anæmia, he may, if warned, proceed to special tests with a view to determining whether an achlorhydria is absolute or whether under additional stimuli the mucosa may be capable of producing some acid.

Normal Curves.

The accepted standard of the normal in fractional gastric analysis is derived from the series of 100 healthy medical students examined by J. A. Ryle and T. I. Bennett, who showed that in 80 per cent. of such subjects the fasting stomach content did not exceed 100 c.cm. and might be almost completely absent; also, that the free HCl fell practically to nil immediately after taking the meal, and subsequently rose to a height somewhere below 50 N/10, falling away from this point during the later time of the investigation. Fig. 1 shows a shaded area within which fall all the readings for free HCl in any of these 80 per cent. of normal subjects, and a curve which conforms roughly to this shaded area must at once be accepted as not differing materially from the normal average.

The Curve of Total Acidity.—This in normal subjects is closely parallel to the curve of free HCl and stands at 10–20 c.cm. higher than the former curve. The two curves are never exactly parallel owing to factors such as regurgitation from the duodenum occasionally diminishing the free HCl without so greatly affecting the total acidity.

It will be observed that the curves, both of free and total acidity, tend to rise during the first hour and to fall subsequently. The shape of the average normal curve calculated from a large series would, therefore, be somewhat as shown in Fig. 2, but the relatively wide shaded area in Fig. 1 makes it clear that a considerable departure from the *average* may occur without anything approaching abnormality being present.

Exceptional "Normal" Curves.

In our study of healthy subjects we observed that extreme deviations from the normal might occur in an important percentage of cases. Thus about 5 per cent. showed a complete absence of HCl with a low total acidity, and about an equal number showed a very abundant secretion with a high concentration of HCl. Although such pictures are most frequently encountered in pathological conditions and will be referred to again in later paragraphs, it must never be forgotten that they may occur in normal men.

TUBERCULOSIS ASSOCIATION.

ANNUAL PROVINCIAL MEETING, CAMBRIDGE, JUNE 27TH–29TH.

THE meeting which was held in the Medical School at Cambridge from Thursday, June 27th, to Saturday, the 29th, was divided into four sessions.

I. THE PREVENTION AND HEALING OF TUBERCULOSIS BY TURTLE-VACCINE THERAPY,

Dr. ERNEST WARD (Paignton) being in the chair,

Dr. FRANZ NAGELSCHMIDT (Berlin) said that if the turtle-vaccine therapy had been used systematically from the time of its discovery by Friedmann, much of the expenditure on the campaign against tuberculosis, which had had relatively meagre results, could have been avoided. For various reasons the method had fallen into early disrepute, but in various countries about three million cases had now been treated by it, and protective inoculation had been extensively carried out, so that we were now in a position to review the results and revise any hasty judgments. The main stated objections to turtle-vaccine therapy were that it was too dangerous, that it was too harmless, that the tuberculous lesions would have healed just as well without the vaccine, and, finally, that many of the cases so treated were not tuberculous. Since 1922, the opponents of the vaccine had ceased to say that it was dangerous or that the bacilli might become virulent; on the other hand, it was evidently not inert, as witness the report of the American Board of Health, and the experimental results of guinea-pig immunisation against tuberculosis by Aronson in 1914, and by Rabinovitch, Klebs, Klemperer, and Reichenbach. It would be difficult to refute the objection that the cases would have healed just as well without vaccination, but Szalai, in Hungary, had inoculated with turtle-vaccine more than 15,000 patients in the last few years, and had lowered the death-rate from tuberculosis by more than 60 per cent. Willies, in dealing with a heavily infected group of 75 baboons, had vaccinated 35 of them; 40 were unvaccinated, and all died; whereas of the 35 vaccinated ones only one, which had very advanced tuberculosis, died. All the others healed or kept well, except two which fell from a rock in the Hagenbeck Zoo. Autopsies on these animals showed that they were free from tuberculosis. The last objection—viz., that the vaccinated cases were not tuberculous at all—did not require serious refutation.

The Nature of the Vaccine.

Vaccination with the turtle tubercle bacillus, published by Friedmann in 1912, was fundamentally different from vaccination with extracts of bacteria or of dead tubercle bacilli. It represented an active immunisation with a species of living tubercle bacilli which was avirulent for warm-blooded animals. The bacillus was not a saprophyte, and it could live long enough in the human or animal body to produce strong and lasting immunising effects. Other species of tubercle bacilli were of no use for this purpose. The living tubercle bacillus of human and bovine origin must be rejected because, even in a weakened form, it could become virulent by injection into the human or animal body. Up to the present time only the turtle tubercle stock grown in 1903 from the tuberculous lungs of a sea-turtle with spontaneously acquired tuberculosis answered all the demands that a tubercle vaccine suitable for men and other warm-blooded animals should fulfil. The turtle tubercle bacillus was non-pathogenic in the bodies of warm-blooded animals; the optimum temperature for its culture was 98·6° F., and it could be kept alive or active in the human or animal body for many months or years. The turtle bacillus stock had not changed biologically since its original culture. The characteristics of growth on artificial media, its ability to create immunity against tuberculosis of bovine or human character in warm-blooded animals, and to heal non-advanced tuberculosis had not been changed. So that it was a real "virus fixe." Even though the turtle vaccine was not able to produce a tuberculosis of the human or bovine type, it could produce an immunity to both types. This was shown by the fact that individuals giving a negative reaction to tuberculin generally reacted positively to prophylactic or curative turtle vaccination.

In regard to the prophylactic power of the turtle vaccine, Dr. Nagelschmidt cited the case of two parents with open tuberculosis who had five children, the first and last of whom were vaccinated. The intermediate three children all died of tuberculous meningitis. In all the later literature no case showing harmful results following vaccination had been published.

Technique.

In order to get the best results with the vaccine, said Dr. Nagelschmidt, it was important to follow Friedmann's directions exactly. Patients with tuberculous cachexia, with multiple tuberculous foci, generalised tuberculosis and meningitis, &c., were unsuitable for such treatment. Children with tuberculous lesions, on the other hand, showed striking improvement, as, for example, in fistulæ, and in bone, joint, and gland tuberculosis.

The vaccine was prepared under the supervision of Prof. Kruss, Director of the Leipzig University Institute of Hygiene. It was made in three strengths, varying in the number of bacilli to the ampoule, the grades being labelled "very weak," "weak," and "strong." The contents of each ampoule were about 0·5 to 0·7 c.cm. The injections were made subcutaneously, the site of election being 2–3 inches behind the greater trochanter. Intravenous injection was made only in special cases; as for example, in early and encapsulated tuberculosis of joints; recent and closed spondylitis without abscess formation; Poncet's tuberculous rheumatism of joints; recent tuberculous iritis, choroiditis, uveitis, and episcleritis; early unilateral renal tuberculosis; tuberculous orchitis, and epididymitis, with or without fistulæ. The treatment advised in these cases was an intravenous injection of 0·1 to 0·5 c.cm. "weak," together with a subcutaneous injection of 0·1 to 0·5 "strong."

Prophylactic vaccination might be undertaken if possible immediately after birth. Infants should receive 0·5 c.cm. "weak." In somewhat older children with small tuberculous foci the dose should be 0·5 c.cm. "very weak." The protection thus set up lasted for 10 to 12 years, but might cease sooner in cases exposed to massive, virulent, or frequent infection. Intercurrent infections, such as influenza and whooping-cough, destroyed the immunity, and in such case revaccination should be carried out. Revaccination should also be done in the event of the development *of a tuberculous focus.*

In surgical tuberculosis, the only cases not suitable for treatment were those which had, or were suspected to have, closed and deep-seated abscesses. If, however, these abscesses were about to perforate or were near the skin surface, they could be opened surgically, allowed to form fistulæ, and six weeks later an injection of turtle vaccine could be given. An alternative method was to give an injection of vaccine at once, and the abscess allowed to perforate spontaneously. After vaccination cold abscesses flared up, perforated, and then healed.

A local tissue reaction at the site of injection was noticed in some cases consisting of small abscesses or the formation of granulation tissue containing giant cells and turtle tubercle bacilli. The appearance or non-appearance of a local tissue reaction was not always essential for a prognosis, but its character was often a useful guide in the further treatment of the case.

In pulmonary tuberculosis the more chronic and inactive the disease the smaller the dose given, the more active the disease the larger the dose.

Experiment on a Large Scale in Prophylaxis and Treatment.

Dr. Nagelschmidt then described an experiment conducted in Pest-erzsebet, a suburb of Budapest. It was, he said, a manufacturing town of about 60,000 inhabitants, with approximately 90 per cent. of workmen. The people were very poor, and the houses were mostly very miserable and very damp. Six to nine people often shared one room. Two to three slept in one bed, many on the floor. The town had no money to support people out of work, or to supply them with food and milk. The conditions were *incredible in a civilised country.*

A physician of the town, Dr. Eugen Szalai, heard of the turtle vaccine method, went to Berlin to study it, and then gave about 2000 vaccinations in 1922. Soon after this a period of famine, revolution, and inflation ensued, and his work was interrupted until July, 1925. At this time Dr. Szalai introduced compulsory notification of cases of tuberculosis, clinically diagnosed as well as open cases, and again instituted the turtle vaccine therapy and prophylaxis. No other method of treatment was used, and the results were striking.

In the whole of Hungary there were 62 towns with more than 10,000 inhabitants (in 1922 there were 49). These 62 cities had in 1923 an average mortality from tuberculosis of 23 in 10,000. Pest-erzsebet had 39 deaths per 10,000. In 1928 Pest-erzsebet had only 18 deaths as against 28·8 in Budapest, and an average of 20·4 in the 62 towns. In 1923 Pest-erzsebet held the thirty-seventh place among the 62 Hungarian towns and to-day it took the sixth place. Dr. Nagelschmidt was confident that at the end of the present year it would hold the first place. The physicians of Pest-erzsebet stated that cases of advanced tuberculosis were now rarely seen. This was the first experiment with turtle vaccine therapy on a large scale in one administrative area.

In the years 1925, 1926, and 1927 *4812* cases of *pulmonary* tuberculosis in the first stage were treated. Of these 12 died, 9 became worse, and the remainder were cured. 216 cases in the third stage were vaccinated. Of these 67 died, 23 cases became progressively worse, and 100 resumed their work. 126 cases of the third stage were not treated with vaccine. Of these 115 were dead and 10 became worse; not a single case improved.

In conclusion, *Dr. Nagelschmidt said that* no untoward results had followed the vaccination; that in really early cases of tuberculosis the percentage of clinical healing reached 98 per cent.; that in tuberculosis of infants healing almost always occurred; and that turtle vaccination should be tried in almost all cases of surgical tuberculosis, for operative measures could often be avoided by its judicious use.

Discussion.

The CHAIRMAN said he would like to have heard more about Dr. Nagelschmidt's own cases, and also about the cases treated in this country. He remembered that about 1913 there were three vaccines of live avirulent tubercle bacilli in use—viz., those of *Friedmann*, Calmette, and Nathan Raw. In his opinion the results of treatment were not impressive. It was an unfortunate feature of all the "cures" for tuberculosis that they only gave good results in early cases. He asked Dr. Nagelschmidt how the vaccine was prepared, what was the correct method of dosage, and how many bacilli there were in each ampoule.

Dr. S. VERE PEARSON (Mundesley) asked how much publicity had been given to the method of preparation. As far as he recollected, the method of preparation of the Friedmann vaccine had not been published in full. He inquired why the turtle tubercle bacillus had been chosen for the vaccine in preference to avian and reptilian bacilli.

Dr. F. R. WALTERS (Farnham) expressed the view that it was a great drawback if a remedy was only available for early cases, and emphasised the tendency to spontaneous cure in tuberculosis. He looked forward to the publishing of further evidence.

Dr. W. H. DICKINSON (Newcastle-on-Tyne) felt that the results given by Dr. Nagelschmidt were almost too good to be true. He had seen ten cases air. She agreed with Dr. Agassiz, that there was a marked contrast between the radiographic and physical signs in *non-tuberculous fibrosis* of the lung.

Dr. George Jessel (Lancashire) agreed with Dr. Burton Wood that the tuberculous child was not the precursor of the adolescent consumptive, and that in the diagnosis of intrathoracic tuberculosis common sense and not far-fetched physical signs were necessary.

Dr. Esther Carling (Peppard Common) wished to know what was going to be done about the child wrongly diagnosed as tuberculous. All of them could not be sent to open-air schools, because these were only to be had in the large towns. In her opinion, delicate children should be treated in sanatoria without notification.

Dr. Ward was in accord with the prevalent view about the value of paravertebral dullness. From the practical point of view one need not wait for elaborate tests to be done before treating a delicate child.

Dr. W. C. Fowler (Pinewood) thought that negative Pirquet cases should be treated rather than cases giving a positive reaction, which he regarded as an indication of protection against tuberculosis.

Dr. Herbert said that the question of physical signs in enlarged mediastinal glands needed further investigation. Although he did not very often find paravertebral dullness in children's chests, one could not, he thought, arbitrarily dismiss the sign as valueless. The dullness might not be due to the actual presence of glands, but to some reflex irritation. Dr. A. I. G. McLaughlin and he were at present engaged in the analysis of a series of cases in order to estimate if possible the value of the various signs said to indicate the presence of enlarged mediastinal glands.

Dr. Margaret Sharp (Bradford) and Dr. Niven Robertson (Chesterfield) were both sceptical about the value of paravertebral dullness, and the latter thought the diagnosis of intrathoracic disease in children an extremely shady business, although he admitted that the use of lipiodol made a very pretty radiogram.

Dr. G. M. Mayberry (Dagenham) said that he had not heard the importance of temperatures in diagnosis emphasised as much as he would have liked, and drew attention to the number of cases of so-called tuberculosis cured by attention to the tonsils and adenoids.

Dr. Pearson thought that there was a great difference to be observed in the incidence and type of tuberculosis in children between 1 and 4 years and after that period. He also stressed the value of taking rectal temperatures.

Dr. Dickinson said that in his experience patients with bronchitis did not readily develop tuberculosis.

Dr. C. H. C. Toussaint (London) stated that in a series of 60 cases labelled as tuberculosis in childhood he knew of only two who had developed true pulmonary tuberculosis in early adult life. It seemed that we might be compelled to change our views and direct more attention to the young adult contact who appeared to be in good health, but who might well be in the latent stages of pulmonary tuberculosis.

The question of tuberculosis in childhood was of great administrative importance. It seemed to be the unanimous opinion of the meeting that there had been gross over-diagnosis of the condition, and if this were so much money had been and more still was being wasted on *treatment*. In London difficulty was arising owing to the fact that the County Council had limited certain open-air schools to notified cases of tuberculosis. Dr. Toussaint considered this to be a great mistake.

[The report of the two remaining sessions is unavoidably held over. These dealt with III. The Correlation of X Ray Findings in Pulmonary Tuberculosis, and IV. Gas Poisoning and Gunshot Wounds of the Chest in relation to Tuberculosis.]

A NATIONAL CAMPAIGN AGAINST RHEUMATISM.

At a meeting held in London at the house of the Royal Society of Medicine on June 20th, a new association having for its object an organised campaign against rheumatic diseases was inaugurated under the title of The National Association for Combating Rheumatism. Sir Thomas Horder took the chair.

Letters of approval and encouragement were received from Sir George Newman (Chief Medical Officer of the Ministry of Health) and others and were put before the meeting by Dr. M. B. Ray, the acting hon. secretary, who also read the proposed constitution and policy of the Association. This emphasised the great crippling effect of rheumatic diseases on a large section of the community, and the important part they were playing in the production of sickness and suffering. It was felt by those responsible for starting the campaign that it was high time to make a concerted effort to deal effectively with the problem in all its aspects. About one-sixth of the total invalidity of the country could be charged to diseases commonly classed as "rheumatic"; they were responsible for the loss of three million weeks of labour, and for the payment of about two million pounds in sick benefit annually. At present there were proper treatment facilities for only a minority of sufferers, and it was felt that, since the causes of these conditions were still obscure, adequate facilities for research as well as for treatment should be provided. In the forefront of the Association's policy was placed the need for educating medical opinion upon early diagnosis and the importance of continuous treatment. The public should be told of the value of further research, whilst efforts directed towards prevention were essential. A system of following up cases needed to be organised, and efficient home treatment should be carried out. Bound up with this was advice about suitability of occupation, in which employers of labour might well be invited to interest themselves. Climatic and occupational factors must be carefully studied, and research must not be confined to the laboratory. Coöperation was required between the laboratory worker, the clinician, the biochemist, and the radiologist, and social workers also should be interested in the campaign. It was hoped that a system of uniform reporting of results would be arrived at; this would certainly aid the collection of statistics, and enable the value of various forms of treatment to be assessed. Another proposal was the establishment of treatment centres.

Sir Claude Hill (Governor of the Isle of Man) formally moved that the Association adopt the proposed constitution and policy, and said that he was much impressed by the scope of the campaign now being undertaken. He hoped industrial interests would be successfully enlisted, and especially that clinics in different parts of the country would be established for dealing with these diseases. He also suggested that the organising secretary should be a man who would be able to travel, so as to ensure the sympathy of the industrialists, and persuade them that their support was needed. The Association, on the suggested lines, would be in a good position to meet what everyone cognisant of the facts would feel to be a real need.

Dr. Malcolm Campbell (Droitwich) seconded the resolution, and mentioned the great aid in the movement which could be afforded by the various women's organisations.

The Chairman agreed about the desirability of a close liaison between the industrial and the purely medical aspects of the problem, and said this had been in the minds of the Committee from the start. He mentioned that the Prime Minister had signified his willingness to become a member of the Council.

Mr. Henry Lesser (President of the National Association of Insurance Committees) moved the acceptance of a list of 71 ladies and gentlemen proposed as members of the Council.

Dr. E. J. SPRIGGS, in seconding, said that in discussing this matter with people and trying to get their help he had found it useful to point out that this was not a charitable appeal. Though rheumatism affected certain classes, no social grade was exempt. It was not proposed to start a new organisation which should replace or absorb any in existence, but one which should coöperate with other bodies for the prevention and adequate treatment of rheumatism. Much good work was already being done and it was "bad business" to have it done in different places separately.

The list of names was then accepted by the meeting.

Dr. FORTESCUE FOX emphasised the need of enlisting all who could help this important movement forward, and hoped that the international aspect would be borne in mind. Good work in this connexion was going on in other European countries.

Dr. J. VAN BREEMEN (Amsterdam), speaking as hon. secretary of the Ligue Internationale contre le Rheumatisme, referred to the Ligue's meeting to be held in October at Budapest, at which ten nations were already represented. Among points on which information from all sources would be welcomed were: the relation between acute and chronic rheumatism and the significance of serological and blood examinations. It would be a great help to receive for consideration at the Congress information and suggestions from England.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

The Water-supply.

THE amounts of water in the Edinburgh reservoir are still extremely low and the Water Committee find it necessary to issue another warning. It is suggested that the consumers should aim at saving 2 gallons a day, which in the population supplied in the Edinburgh area would mean a saving of 1,000,000 gallons daily or 30,000,000 gallons a month. It was pointed out by the engineer that the use of water for flushing the drains and sewers is not wasteful but a necessary health provision, and the amount so used is comparatively small. The aqueduct from the Talla reservoir is being duplicated; but the duplication cannot be finished in time to relieve the situation this year. The manager of the Glasgow Water Department says that earlier in the year there was some anxiety, but at present there is an assured supply for four months. The notices posted in the tramcars some time ago calling upon the citizens to conserve the supply as much as possible seem to have had an effect.

Finances of Edinburgh University.

At a recent meeting of the University Court Sir Alfred Ewing, the Principal, said that the ordinary revenue had increased from £110,000 in 1913–14 to nearly £250,000 in 1927–28, and in the current session it would probably be £251,000. In these figures no account is taken of scholarships or bursaries for which the University is only a trustee. Of the whole regular income, about £48,000 comes as interest from endowments, Parliamentary grants amount to £91,800, and £107,000 is paid in fees. The ordinary revenue includes also about £9000 in donations and subscriptions (apart from capital donations), and in payments by local authorities for services rendered. Of disbursements the salaries of the teaching staff constitute the heaviest item—about £141,000. Pensions and contributions to the federated superannuation scheme account for £15,000; wages and grants to departments for expenses require £25,000, and libraries and museums about £9000. The cost of administration, including the salaries of the Principal and of members of the secretarial staff, is about £18,000. Some £30,000 is required for maintenance of premises, and £10,000 for alteration and adaptation of buildings, and for certain apparatus and equipment. The whole expenditure charged to the ordinary account for 1927–28 was about £253,000, leaving a deficit on the year's working of £3190. For the current year the estimated deficit is £1670, and is likely to be more. Sir Alfred pointed out that enlargement of the University, in respect of buildings, subjects, and staff, cannot fail to increase the annual charges that fall on ordinary revenue. As a rule, the increase in revenue from fees arising from a new development does not compensate for the increase in annual charges. Hence new sources of revenue must be found. It is for consideration whether, in the disposal of future capital grants from the Carnegie Trust, the trustees should not be invited to consider the wisdom of giving some relief from the increasing burden of maintenance, by granting sums for the better endowment of existing professorships and lectureships, whose value is established, but whose cost is now a burden on the general funds. The bequests and gifts which have made the expansion of the University possible have amounted to over £1,174,000 since 1918. Fully half of this has been invested to provide endowments for particular or general purposes, whilst the remainder has been or is being applied to various extensions of premises and work, including provision for an extensive and much-needed reconstruction of the Medical School.

An Auxiliary Hospital in the Country.

The Auxiliary Hospital of the Victoria Infirmary, Glasgow, at Philipshill, near Busby, was formally opened on June 27th. Beautifully situated in rural scenery, the grounds of the extension cover some 33 acres, and two of the eight pavilions which will ultimately be in use are now completed. It will serve as a convalescent hospital where patients, having passed the stage for constant medical and surgical attention, can be transferred to convalesce, and thereby release beds for the long list of sufferers awaiting admission to the infirmary.

Mr. William Gray, who presided, said that the natural evolution of hospital treatment seemed to demand that buildings in the cities should be regarded as clearing-houses for cases in the acute stage; when that stage had been passed the patients should be placed in brighter and more attractive surroundings than the ward of a city hospital. They would not have been able to proceed with the work if Mr. Gilchrist Macbeth had not offered to contribute £20,000 if it was undertaken. Miss Innes had contributed £13,000 for the building of a chapel and to defray the cost of a ward.

Major Walter Elliot, M.P., late Under Secretary of State for Scotland, who gave an address on the general hospital problem, spoke of the damaging effect of urban noise on minds and tempers. If this problem could not be solved for the healthy, let an attempt at least be made to solve it for the sick. Glasgow was on the verge of a further expansion and the governors of the hospital were to be commended for having got a little ahead of the procession which would shortly follow out of the city. Such expansion had been in the mind of the late administration in considering Scottish local government and the relation between the voluntary, city, and parish hospitals. Not only had the hospitals of Glasgow to be treated as a unit, but extensions outside the area had to be recognised as part of the system. The decision that public hospitals should be under one health authority meant that its relations with the voluntary hospitals must be closer than before, and by submission of local reorganisation schemes to the Department of Health it was hoped that overlapping might be avoided. He was certain that they could always look to the central department and to the present Secretary of State for Scotland for sound reasoned judgment on these great matters.

EPSOM COLLEGE.

THE annual general meeting of the Governors of Epsom College was held on Friday, June 28th, at the Office, 49, Bedford-square, W.C., when the Chairman of the Council, Dr. Raymond Crawfurd, presided.

The report of the scrutineers showed that the following were the successful candidates for pensionships and foundation scholarships:—

Pensionerships.

	Votes.		Votes.
*Mylan, Dr. James G. ..	6723	‡Alford, Mrs. Mary A...	5417
*Johnstone, Dr. George W.	5930	†Benson, Dr. Alfred ..	4897
*Ogilvy - Ramsay, Mrs. Isabella	5673	‡Harris, Dr. Arthur G. R.	4584

* Ordinary Pensioners. † Highett Pensioner.
‡ Burney Yeo Pensioners.

Foundation Scholarships.

Porter, John D.	21,027	Hogg, Robert D. ..	13,926

In proposing the adoption of the report and the income and expenditure account, the Chairman expressed the Council's regret that three warm friends of the College had died since the last annual general meeting—namely, Lord Rosebery, who was President, Dr. Francis de Havilland Hall, who was a Vice-President and for some time acted as Vice-Chairman of the Council, and Mr. Æneas Mackay, who was a member of the Council. Dr. Crawfurd stated that the sum of money required for the new sanatorium was not increasing as rapidly as the Council would wish, and he urged all friends of the College to procure donations for this special purpose. He added that if two sums of £5000 could be obtained the work would be started at once. In reference to the school, he said that progress was being made in all directions, and that the Council had brought into force a much improved scale of salaries and emoluments for assistant masters, and this had been greatly appreciated. The Council had received with great pleasure a sum of £1000 which Lord Beaverbrook had placed at the disposal of Mr. Stanley Baldwin in gratitude for his escape, as well as the escape of his associates, in a motor accident. This generous gift was being expended on the furtherance of scientific education at the College.

The report submitted to the Governors showed that since the last annual general meeting an open entrance scholarship of £100 per annum in classics at Pembroke College, Oxford, had been won by E. V. E. White. Eighteen candidates entered for the first examination for medical degrees, as follows:—London, 11 candidates, of whom 4 were completely successful, 5 were successful in two subjects out of three and 1 was successful in one subject out of three; Oxford, 2 candidates, both of whom were completely successful; and Cambridge, 5 candidates, 4 of whom were successful in all subjects, and 1 was successful in one subject. Sixteen candidates presented themselves for the University of London higher certificate, of whom 6 were completely successful and 8 were partially successful, whilst 8 candidates out of 12 were successful at the University of London matriculation examination. Of 87 boys who presented themselves for the University of London general school examination, 76 gained school certificates, 8 with honours, of whom 42 gained exemption from matriculation. Thirty-three boys obtained the War Office certificate "A"; out of 3 candidates for the Royal Military College, Sandhurst, 2 were successful, gaining 3rd and 70th places; and 1 boy was successful for the Royal Navy paymaster cadetship, taking the 6th place. The report further stated that A. L. Novis had been awarded his "cap" for England, being the second Old Epsomian to win his Rugby international during the last two years; W. J. Leaning had been elected captain of the Oxford University boxing team, and D. L. Rhys had represented Sandhurst in cricket, boxing, and fencing.

The Governors were able to elect only nine members of the Council to serve for a further period of three years, instead of ten as prescribed by the Act of Incorporation, owing to the death of one of the candidates, and it was decided to adjourn the meeting until Friday, July 26th, when a tenth member would be elected.

ELECTION OF DIRECT REPRESENTATIVES FOR THE DENTAL BOARD OF THE UNITED KINGDOM.

THE second election of direct representatives for the Dental Board of the United Kingdom took place last month, the votes being counted on June 17th–19th.

(a) Qualified Dentists Practising in England and Wales (2 Seats).

Four candidates were nominated—namely: Mr. W. R. Ackland, L.D.S., M.R.C.S.; Mr. W. H. Dolamore, L.D.S., M.R.C.S.; Mr. W. H. Gilmour, L.D.S.; and Mr. C. F. Rilot, L.D.S., M.R.C.S.

The number of voting papers issued was 5926; deducting dead letters (20) the possible number of voters was 5906; good votes numbered 3207; invalid votes (the larger part on account of failure to sign the identification envelope) 364, and 2335 took no part in the election.

The voting papers were sorted according to the first choices, and then, as the voting for the third place was seen to be so close, a further count was taken. The result was as follows: Ackland, 828; Dolamore, 1032; Gilmour, 679; Rilot, 668; total, 3207. The quota (one more than a third of the whole) was 1070. As no one had obtained the quota Mr. Rilot, having received the least number of votes, was declared defeated, and his votes transferred to the second choices shown on his papers. This produced the following result: Ackland, 925; Dolamore, 1509; Gilmour, 763; non-transferable, 10; total, 3207.

Mr. Dolamore had now obtained the quota, and he was declared to be elected, his surplus votes (439) being transferred to the candidate marked 2 on his papers in such a manner that each received his proper proportion. The result was shown to be: Ackland, 1056; Gilmour, 874; non-transferable, 207; retained for Dolamore's quota, 1070; total, 3207. Mr. Ackland was therefore declared to be elected.

No. of valid votes, 3207. No. of members to be elected, 2.

$$\text{Quota} = \frac{3207}{3} + 1 = 1070.$$

Names of candidates.	First count.	Second count.		Third count.	
	Votes polled by each candidate.	Transfer of Rilot's votes.	Result.	Transfer of Dolamore's surplus.	Result.
ACKLAND ..	828	+ 97	925	+131	1056
DOLAMORE ..	1032	+477	1509	—439	1070
Gilmour.. ..	679	+ 84	763	+111	874
Rilot	668	—668	—	—	—
Non-transferable papers ..	—	+ 10	10	+197	207
Totals.. ..	3207	—	3207	—	3207

(b) Qualified Dentists Practising in Scotland (1 Seat).

Two candidates were nominated—namely: Mr. W. Guy, L.D.S., F.R.C.S., and Mr. J. W. A. McGowan, L.D.S.

The number of voting papers issued was 925; deducting dead letters (5) the possible number of voters was 920; good votes numbered 660, invalid votes 60, and 200 took no part in the election.

The result was as follows: McGowan (elected), 301; Guy, 209.

(c) Qualified Dentists Practising in Ireland (1 Seat).

Two candidates were nominated—namely: Mr. J. Malone, L.D.S., and Mr. E. L. Sheridan, L.D.S., F.R.C.S.

The number of voting papers issued was 296 and there were no dead letters; good votes numbered 196, invalid votes 13, and 87 took no part in the election. The result was as follows: Sheridan (elected), 124; Malone 72.

(d) Dentists, 1921 (2 Seats).

Four candidates were nominated—namely: Mr. W. F. Bowen (Bolton), Mr. F. Butterfield (Lytham, Lancs.); Mr. A. H. Condry (Birmingham), and Mr. W. L. Edwards (Gloucester).

The number of voting papers issued was 7222; deducting dead letters (16) the possible number of voters was 7206; good votes numbered 3787 (4178); invalid votes (the larger part again on account of failure to sign the identification envelope) 399, and 3020 took no part in the election.

The voting papers were sorted according to the first choices, the result being as follows: Bowen, 855; Butterfield, 1820; Condry, 281; Edwards, 831. The quota (one more than a third of the whole) was 1263.

Mr. Butterfield, having obtained more than the quota, was declared to be elected, and his surplus votes (557) were transferred to the second choices. For this purpose all Mr. Butterfield's papers were re-examined, counted, and transferred in such a way that each candidate named as a second choice received the same proportionate share.

The result after the transfer of Mr. Butterfield's surplus was: Bowen, 1159; Condry, 419; Edwards, 946; quota retained for Butterfield, 1263; total, 3787.

As none of the other candidates had yet obtained the quota Condry was declared defeated and his votes transferred according to the preference, where expressed, to Bowen or Edwards. The result of this transfer was: Bowen, 1355; Edwards, 1117; non-transferable, 52; quota retained for Butterfield, 1263; total 3787. Mr. Bowen was therefore declared to be elected.

No. of valid votes, 3787. No. of members to be elected, 2.

$$\text{Quota} = \frac{3787}{3} + 1 = 1263.$$

Names of candidates.	First count.	Second count.		Third count.	
	Votes polled by each candidate.	Transfer of Butterfield's surplus.	Result.	Transfer of Condry's votes.	Result.
BOWEN	855	+304	1159	+196	1355
BUTTERFIELD ..	1820	—557	1263	—	1263
Condry	281	+138	419	—419	—
Edwards ..	831	+115	946	+171	1117
Non-transferable papers ..	—	—	—	+52	52
Totals.. ..	3787	—	3787	—	3787

Comments.

The total percentage of the electorate who took part in the election was 60·55 per cent., as compared with 64·49 in 1924. It was shown in this election, as in 1924, that it is not good policy to refrain from recording the order of preference for all the candidates. Those who recorded only their first choice took no part in the election of the candidate when it came to taking further counts, and their papers merely became "non-transferable." The sorting and counting of votes, and the necessary calculations were carried out under the direction of Mr. A. J. Gray, of the Proportional Representation Society.

Correspondence.

"Audi alteram partem."

THE MECHANISM OF FILARIAL PERIODICITY.

To the Editor of THE LANCET.

SIR,—The thoughtful and stimulating article by Colonel Clayton Lane on the mechanism of filarial periodicity in your issue of June 22nd has once more raised interest, at a most appropriate time, in this mysterious phenomenon. As Colonel Lane has done me honour by frequently referring to my own contributions on the subject (made some 17 years ago), I have thought it appropriate that I should set down some of my own views. There is nothing that I regret so much in my work on filariasis in Fiji that, apart from making certain observations on the lack of periodicity of the Fijian microfilaria and tracing its development in its appropriate intermediary host, I was unable to finally determine the exact mechanism of periodicity, except to assume (as had Manson in his original discovery) that this habit was an adaptation to the peculiarities of the mosquito host. This conclusion, which at that time appeared tenable on purely biological grounds, is not, as Colonel Lane has shown, so simple as it at first sight appeared to be. Colonel Lane sums up in favour of simultaneous cyclical parturition on the part of the female filaria as the cause of periodicity—that is to say, he assumes that in the case of the nocturnal *F. bancrofti*, the embryos are emitted by the parent worm into the blood stream during the night time, while in the non-periodic *F. bancrofti*, of Fiji and of Oceania in general, the embryos filter into the blood during the whole of the 24 hours, and that daily enormous numbers of microfilariæ are destroyed in and disposed of by the human body. In order that this supposition should fit in with the facts so far as they are known, we must credit each female *F. bancrofti* with extensive powers of fecundity. It is the only explanation at present forthcoming which will even roughly correspond with the known facts; but in order to explain the very large numbers of microfilariæ which may be found in the peripheral circulation of an individual, it is necessary to know the total volume of blood in the peripheral circulation on the surface of the body to which microfilariæ have access. This is an extremely difficult matter to ascertain accurately, and, even if we can do so roughly, there remains the uncertainty of the proportion of microfilariæ in the larger blood vessels.

As Fülleborn[1] states, it is readily understood that microfilariæ are held up in the smaller terminal capillaries, especially during their periodic appearances, but that they are more generally distributed throughout the larger arteries and veins also appears probable. Mackenzie and others have attempted to reckon out the total numbers of microfilariæ present in the blood of an average infected case as 40 to 50 millions, but these are mere guesses. I have had the assistance of Dr. W. K. Blackie in endeavouring to calculate out the amount of blood present in the peripheral circulation of an adult, 6 ft. in height, of 11 st. 6 lb. 12 oz. in weight, and with a surface area of 1·9 square metres. Assuming the blood volume to be 5 litres, the amount in the peripheral circulation would be 203 c.cm. I have frequently recorded in my work in Fiji counts of over 500 microfilariæ to every 20 c.mm. of blood, or one microfilaria to every 20,000 red blood corpuscles. On this basis of reckoning, in the skin and subcutaneous tissue to a depth of 2 mm., there are contained no less than 6,575,000 microfilariæ. I have no means of ascertaining accurately the number of fecund and mature

---

[1] Fülleborn, F.: Filariosen des Menschen, Hand. d. Path. Mikro-org., 1929, p. 1103.

F. bancrofti present in a filariated individual at the one time. From such autopsies as I have been able to perform I should not place it at a figure higher than 20, which, if the periodic daily destruction of microfilariæ takes place, would credit a single female *F. bancrofti* with the power of producing some 328,000 embryos daily. Whether this is possible or not I do not think we are in a position to say. That certain helminths are prodigal in their reproductive capacity is well known, but I doubt whether there are any figures of the reproductive capacity in nematodes which would compare with these. As Clayton Lane suggests, some method of comparison might be obtained by a more minute study of allied species, such as the filariæ of birds of which the adults can be found and counted with greater certainty in the body than can the human species. Once only have I had the opportunity of watching the female *F. bancrofti* in the act of parturition, and this was, of course, under artificial conditions in a watch-glass in normal saline solution. The embryos emerged from the vulva in an unending stream, but it was impossible at the time for me to even estimate their numbers. I have hitherto hesitated in accepting the cyclical parturition theory, mainly on account of the only properly conducted experiments on the longevity of microfilariæ in the blood which were carried out by Fülleborn and which placed the life span of microfilaria repens of the dog, apart from the adult, at about two years. It may be, as Colonel Lane suggests, there was some flaw which vitiated the experiment. If his supposition of the daily destruction of millions of microfilariæ in the human body is correct, there must be some method of the disposal of their remains. One would expect that some evident pathological lesions would be produced. But this does not appear to be so. The fact remains that, from a clinical standpoint, those individuals with the highest microfilariæ count show fewest signs of what is generally understood as filarial disease. On Clayton Lane's hypothesis this would really indicate that the parent filariæ are located in some situation favourable to the uninterrupted passage of microfilariæ into the blood stream.

How can this question be determined? As far as is at present known there is no experimental animal in whose blood microfilaria bancrofti can survive. There only remains man himself, so that I would suggest that no great difficulty should be experienced in injecting a sufficient number of live M. bancrofti into a suitable volunteer in this country, so that by these means its life span could be determined and the conditions of Fülleborn's experiment reproduced. On the analogy of the embryos of other parasitic helminths it would be unbiological for the life span of microfilariæ in the blood stream to be a long one.

My mind is somewhat exercised to know how to fit in all the known facts with the theory of cyclical parturition. Let us recapitulate what they are: there are two varieties of *F. bancrofti* in man, morphologically indistinguishable from one another, each possessing a distinct geographical distribution, producing identical embryos, one with nocturnal periodicity, the other exhibiting no periodicity, developing in different species of mosquito intermediary hosts, and maintaining a different habitat in the human body. The latter is a point upon which insufficient emphasis has been laid. In the nocturnal *F. bancrofti* infections, the adults appear to live in the main lymphatic trunks in the neighbourhood of the thoracic duct, whence, presumably, they can pour an uninterrupted stream of embryos into the blood stream; in other words, they maintain a central location. Hence manifestations of disease brought about by lymphatic obstruction of the main trunk, such as chyluria, are associated with the nocturnally periodic *F. bancrofti*. On the other hand, the non-periodic *F. bancrofti* of Oceania inhabits the lymphatic glands, epididymis, tunica vaginalis, and perhaps the organs of the body. *It maintains a peripheral distribution.* Hence the filarial diseases produced are mainly those of enlarged lymphatic glands and the obstruction they give rise to. Chyluria is *completely* absent and elephantiasis of the forearm, extremely rare in other regions, is common and is due to the infestation of the epitrochlear glands by adult filariæ. How would this fit in with the theory of cyclical parturition? I can conceive that it does so by the fact that the embryos produced in the substance of the lymphatic glands have a much more complicated and circuitous route to pursue before they reach the blood stream which they enter by a constant trickle and thence appear in the peripheral blood capillaries in equal numbers both by day and by night. The next question which naturally arises is, how can one reconcile cyclical parturition with the inversion of periodicity in the nocturnal *F. bancrofti* by altering the sleeping habits of the host, as first shown by Mackenzie and afterwards confirmed by Manson? This is only explicable by the supposition that there is some substance in the blood of the sleeping host which has a stimulating effect upon the reproductive organs of the female parturient filaria. But how can that be reconciled with the diametrically opposite case of the diurnal *Loa loa* in which the embryos appear in the same vast numbers in the peripheral blood stream during the hours of daylight? Are we to suppose that in this instance this hypothetical chemical stimulant has the opposite effect? And how is it that the periodicity of the diurnal microfilaria loa cannot be (easily at any rate) upset, though as Külz has demonstrated,[2] this upset of periodicity during the voyage from West Africa to North America actually takes place?

Another difficulty I find in envisaging the entry of the microfilaria loa into the blood stream. How exactly is this brought about, except through the lymph channels? As far as we know, the adults of *Loa loa* live in the connective tissues, but the parturient female must have direct access to the lymph stream before her embryos can enter the blood. Again, in connexion with this last parasite: how can we reconcile the remarkable observations made by Manson and confirmed by myself that subsequent to the date of known infection by *Loa loa* a period of six to seven years may elapse before the entrance of the embryos into the blood takes place. It is inconceivable that it is necessary for this long period before the adult *Loa loa* becomes mature. Rather may we explain it on the supposition that the female or females of *Loa loa* find themselves in a position from which the embryos are unable to find their way into the blood; and it is while they are searching for a suitable breeding ground that they emit the embryos into the connective tissues and cause those curious "Calabar swellings," which may be said to resemble the lesions brought about by the infelicitous discharge of guinea-worm embryos into the body. I would therefore appeal for future study to be directed towards solving these crucial questions by a reconsideration of the mechanism of periodicity on a wider scale, by carefully weighing in the balance all the evidence which has been collected, not on the life-history of *F. bancrofti* alone, but also upon other human species.

Since my work on filariasis in Fiji and Ceylon has been completed I have had few opportunities of continuing observations on periodicity. I was, however, able in 1925 to confirm the observations of Külz that capillary constriction causes no diminution in the number of circulating microfilariæ (*Loa loa*). In this instance blood was taken periodically from a finger immersed in ice and the total number compared to that from the unfrozen member of the opposite hand.

More work is required to bear out conclusions based upon the appearance of microfilariæ in the urine. In pure chyluria such few observations as I have made go to show that the filarial embryos are usually dead by the time they appear in the urine, but in hæmatochyluria, where there has been an outpouring of the blood into the chylous urine, I was able to ascertain from observations made on a case of the disease in a Japanese sailor in December, 1923, that numbers of live microfilariæ appeared in the urine passed at night time only and that they maintained a periodicity strictly parallel to that of the finger blood.

---

[2] Fülleborn: Loc. cit., p. 1109.

We may take it, then, that periodicity is a beautiful adaptation of nature, much more intricate and certainly not more wonderful than the many familiar adaptations in animal and plant life, of which it is possible to quote many examples. Its elucidation will come when all factors of natural history of the parasitic filaria worms are adequately studied and understood, and we may therefore conclude that there is nothing unbiological in the idea that the female filariæ have certain cyclical and well-defined periods for emptying the uterus of the imprisoned embryos.

I am, Sir, yours faithfully,

PHILIP MANSON-BAHR, M.D., F.R.C.P.

Weymouth-street, W., July 1st, 1929.

RIVERS POLLUTION.

To the Editor of THE LANCET.

SIR,—I am very glad to see that your paper has been giving prominence to the growing evil of river pollution, and it is much to be hoped that you will continue to impress upon your readers the importance of this matter. The apathy of all classes of the public to this national danger is very remarkable, and any newspaper which combats this apathy is doing a service to the country. Pollution not only destroys the amenities of the country and causes enormous *annual loss to agriculture and other industries*, but it diminishes the available water-supply and is a menace to the health of the whole population.

Medical men do not need converting to a belief in the evil effects of pollution but they may not fully realise how widespread the evil is and how rapidly it is growing. For example, the Clerk to the Trent Fishery Board lately stated publicly that in the 5000 square miles over which his Board exercised supervision, there was not a single authority that was dealing adequately with its sewage disposal. This is not an isolated case. It is merely an example of what is happening in almost every part of England. It is to the medical profession, more than to any other class, that those who are alive to the danger will look for support and indeed for leadership in the fight. Not only can medical men as individual missionaries preach a crusade against pollution, but collectively as a body, the profession can use the tremendous weight of its influence to press for amendment in our deplorably defective anti-pollution laws and their equally deplorable administration by our Government Departments.

I am, Sir, yours faithfully,

THOS. W. GOMM,

Hon. Secretary, Pure Rivers Society.

Lincoln's Inn-fields, W.C.2, July 1st, 1929.

BICARBONATE FOR BLACKWATER FEVER.

To the Editor of THE LANCET.

SIR,—I would like to support the statement made by Dr. Chesterman in the last paragraph of his paper (THE LANCET, June 29th, p. 1365) regarding the value of oral administration of bicarbonate of soda solution for blackwater fever. When in Kenya Colony I treated one case of blackwater fever in an Indian child 5 years old by that means. Another case of more practical interest is that of a European man aged 46 years, who had a fourth attack at some gold mines in an inaccessible district where there had been just previously two fatal cases. This man promptly retired to bed and consumed as much bicarbonate of soda in water as he could tolerate. Owing to the condition of the roads in the rainy season, it was 48 hours after the onset before I reached him and by that time hæmoglobin had disappeared from the urine and only slight jaundice remained.

It is well recognised that blackwater fever cases stand movement badly, and often, under tropical conditions, cases would have a better chance treated on the spot by such means than by submitting them to a lengthy and tedious journey to a hospital.

I am, Sir, yours faithfully,

C. P. DONNISON, M.B., B.S. Lond.,

Late Medical Officer, East African Medical Service.

Benfleet, Essex, June 28th, 1929.

A FICTITIOUS INTERVIEW.

To the Editor of THE LANCET.

SIR,—At the last meeting of the Urological Section of the Royal Society of Medicine on June 27th I gave, by invitation, a demonstration of motion and sound pictures of operations, and notice of the forthcoming demonstration was published in your issue of the previous week. There has since appeared in the public press a florid account of this demonstration with personal references to myself and a statement that I am supposed to *have* made at an interview. I am writing to assure my professional colleagues that I have had no communication with the press by word or in writing, and that no interview of any sort has taken place. I am taking steps to have this acknowledged by the journal in question.

I am, Sir, yours faithfully,

JOHN THOMSON-WALKER.

Harley-street, W., July 2nd, 1929.

⁂ A brief account of the demonstration appears under the reports of Medical Societies.—ED. L.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED JUNE 22ND, 1929.

Notifications.—The following cases of infectious disease were notified during the week:—Small-pox, 166 (last week 191); scarlet fever, 1786; diphtheria, 1012; enteric fever, 33; pneumonia, 873; puerperal fever, 47; puerperal pyrexia, 69; cerebro-spinal fever, 9; acute poliomyelitis, 2; acute polio-encephalitis, 2; encephalitis lethargica, 25; continued fever, 1; dysentery, 4; ophthalmia neonatorum, 110. No case of cholera, plague, or typhus fever was notified during the week.

The number of cases *in the Infectious Hospitals of the* Metropolitan Asylums Board on June 26th–29th was as follows:—Small-pox, 239 under treatment, 3 under observation (last week 269 and 10 respectively); scarlet fever, 1304; diphtheria, 1581; enteric fever, 13; measles, 181; whooping-cough, 409; puerperal fever, 29 (plus 6 babies), encephalitis lethargica, 121; "other diseases," 41. At St. Margaret's Hospital there were 10 babies (plus 7 mothers) with ophthalmia neonatorum.

Deaths.—In the aggregate of great towns, including London, there was no death from small-pox, 3 (0) from enteric fever, 46 (4) from measles, 4 (0) from scarlet fever, 34 (9) from whooping-cough, 20 (0) from diphtheria, 44 (12) from diarrhœa and enteritis under two years, and 22 (2) from influenza. The figures in parentheses are those for London itself.

Liverpool reported 11 deaths from measles, Leeds 4, Nottingham and Sunderland 3 each. Birmingham reported 5 deaths from whooping-cough, Wigan and Manchester 2 each; no other large town more than 1. Birmingham, Liverpool, and Manchester each reported 4 deaths from diarrhœa and Salford 3.

The number of stillbirths reported during the week was 288 (corresponding to a rate of 40 per 1000 total births), including 60 in London.

JENNY LIND HOSPITAL FOR CHILDREN.—On Saturday last Princess Mary opened a new out-patients' block and special departments in this Norwich hospital.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

The New Parliament.

The new Parliament was opened on Tuesday, July 2nd. Owing to the recent illness of His Majesty The King, it was not thought advisable to submit him to the strain of a State opening, and the ceremony was therefore performed by Royal Commission. The Lords Commissioners were the Lord Chancellor, the Earl of Kintore, Lord Southborough, Archbishop Lord Davidson, and Lord Denman. The King's speech, which was read in the House of Lords by the Lord Chancellor, stated that while His Majesty regretted that it was not possible to address Parliament in person, he thanked Almighty God that he could look forward with confidence to that complete restoration of health for which the prayers of his people throughout the Empire with a sympathy and affection which called forth his deepest gratitude were offered during the months of his long and serious illness. The Government was at present considering the unanimous report of the independent financial experts appointed to draw up proposals for a complete and definitive settlement of the German reparation problem in preparation for a conference of representatives of the Governments concerned. A settlement of this problem would enable the occupying Powers to proceed with the evacuation of the Rhineland. It was the earnest hope of the Government, in coöperation with the Governments of the Dominions of India and of foreign Powers, to ensure an early reduction of armaments throughout the world. Consultations were taking place regarding the signing of the Optional Clause embodied in the statute of the Permanent Court of International Justice. The question of the resumption of diplomatic relations with the Soviet Government of Russia was also being examined. It would be the foremost endeavour of the Government to deal effectively with the continuing evil of unemployment. Schemes were being prepared for the improvement of the means of transport, for the stimulation of the depressed export trades, for the economic development of the overseas Dependencies, for the improvement of the condition of agriculture, for the encouragement of the fishing industry, and for the improvement of the facilities for the marketing of farm and fishery outputs. Measures were being considered in coöperation with the Dominion Governments to provide greater opportunities for overseas migration. Proposals would be submitted to Parliament in due course dealing with the reorganisation of the coal industry, including hours and other factors and the ownership of minerals. Inquiries would be undertaken immediately in order to discover means to coöperate with the iron and steel and cotton industries to improve their position in the markets of the world. Bills would be introduced for amending and consolidating the existing factory legislation and for giving effect to the obligations entered into in Washington in 1919. Legislation would be undertaken to promote an extensive policy of slum clearance and to make further provision for housing in urban and rural areas. The Government had decided that a time had come to investigate the whole field of legislation relating to the sale and supply of intoxicating liquor and commissioners would be appointed for that purpose. A general survey was proceeding of the various National Insurance and Pension schemes. Meanwhile a Bill was being prepared to amend the Widows', Orphans', and Old Age Contributory Pensions Act, 1925, so as to modify the conditions applicable to certain pensions and to make some increase in the classes of persons entitled to them. A measure would be introduced to remedy the situation created by the Trade Disputes and Trade Unions Act, 1927. At the recent General Election an extended franchise placed in the hands of the whole of the people of adult years the grave responsibility for guarding the well-being of the nation as a constitutional democracy, and the Government proposed to institute an examination of the experiences of the election so that the working of the law relating to Parliamentary elections might be brought into conformity with the new conditions.

Manchester Babies' Hospital.—The annual report shows that last year there were 881 admissions and 316 discharges, and that the mortality was 14·59 per cent. The most numerous cases, amounting to practically one-third of the discharges, were those of chronic dyspepsia; of rickets, which came next, there were 42. Prematurity accounted for the largest number of deaths (12). The number of premature children increases every year; in 1924 it was four, but in 1928 it had risen to 37. It has been decided to immunise against diphtheria all infants whose parents are willing.

Medical News.

University of Birmingham.—At a congregation held on June 29th the following degrees and diplomas were conferred:—

M.D.—W. D. Beck and C. G. Payton.

M.B., Ch.B.—*W. C. Smallwood, †E. G. Abdel-Malek, F. A. d'Abreu, Adele M. Frankland, C. W. Kidson, F. G. Lewis, A. J. Moffett, E. H. Parkinson, H. R. Kalra, Ali Said, Christopher St. Johnston, F. R. Smith, George Steane, K. S. Thom, and Doris I. Wall.

* First class honours. † Second class honours.

Diploma in Dental Surgery.—B. D. Britton.

Application is invited for the Walter Myers travelling scholarship of £300 for research in pathology during the year 1929–30. Particulars will be found in our advertisement columns.

University of Durham.—At a Convocation held on June 27th the following degrees and diplomas were conferred:—

M.D.

Max Coll, O. C. Dobson, John Hare, A. H. Holmes, F. W. Marshall, P. M. Rivaz, Gladys Stableforth, A. J. Watson, and Reginald Wear.

M.B., B.S.

Sydney Adler, J. C. Arthur, W. F. Cross, Kenneth Daniels, C. E. Goldberg, H. W. T. Hall, Wilfred Hall, John Maddison, H. D. Ord, A. R. D. Pattison, J. K. H. Scott, J. B. Tilley, and Nora Walkinshaw.

B.Hy. and D.P.H.

Katherine M. Cellan-Jones, O. C. Dobson, and A. J. Watson.

University of Glasgow.—At a ceremony of graduation on June 28th the folllowing degrees were conferred:—

M.D.—*J. S. Young, Moses Cohen, and J. C. H. Mackenzie.

* With honours.

Queen's University, Belfast.—At recent examinations the following candidates were successful:—

M.D.

*Robert Armstrong, *W. H. Belford, Robert Evans, H. E. Hall, †R. A. G. Hamilton, J. B. Lyle, W. J. M'Cracken, W. A. Scott, and H. A. Warnock.

* With commendation. † Gold medal.

M.Ch.

F. S. Carson.

M.B., B.Ch., B.A.O.

First Class Honours.—W. J. Hamilton, T. B. H. Haslitt.

Second Class Honours.—J. S. Baxter, Hugh Caldwell, Joseph Gray, J. V. Hurford, C. J. Lord, James Montgomery, and D. A. C. Wilson.

Pass.—D. R. Cairns, Mary V. Cox, J. C. Craig, C. T. Denny, Charles Dick, J. M'K. Dundee, Mabel G. Hall, D. B. L. Harris, Margaret L. Irvine, Wilson Johnston, Marcus Killen, J. K. M'Collum, W. C. MacFaul, G. J. M'Gouran, J. A. MacHugh, James M'Master, Eveline M'Mordie, A. H. Montgomery, D. M. Quinn, L. F. Ragbir, J. G. Ryan, Thomas Scott, J. P. Thomson, H. B. C. M. Wallace, and Alexander Woods.

University of Leeds.—At a congregation held on July 1st the degree of Doctor of Science, honoris causa, was conferred on Dr. Thomas Wardrop Griffith, Emeritus Professor of Medicine in the University.

Introducing Dr. Griffith, Prof. Veale spoke of his unbroken and close connexion with the Medical School for 46 years. Appointed professor of anatomy in 1883 at the early age of 26, he had at once brought the School of Anatomy to the front rank, and had identified himself with the interests and development of the Medical School in every direction. The present fine premises were largely due to his efforts, and the University owed him a lasting debt of gratitude for the careful planning and sound construction of this building, which, though now being substantially enlarged, would be a lasting memorial of his efforts. In 1910 Dr. Griffith had become professor of medicine, and as a clinical teacher he had shown the same mastery of style as had distinguished him in anatomical science. As a physician he had added much to the prestige of the school and to medical science. As an authority on cardiology, and more particularly the difficult and recondite problems of cardiac arrhythmia, his fame was surely established by accurate and extensive clinical research. Throughout his career he had been distinguished by a personal integrity of the highest order, and unswerving loyalty to the most honourable traditions and ideals of his profession, and a devotion excelled by none to the school which his scientific attainments had done so much to adorn.

The degree of Doctor of Medicine was conferred on G. R. Baxter.

British Homœopathic Congress.—Prince George and the Lord Mayor of London will welcome the delegates to this congress which is opening at the Connaught Rooms, London, to-day, Friday, July 5th, under the presidency of Dr. Thomas Macklin Dishington. It is stated that some 250 American medical men are attending the congress.

St. Bartholomew's Hospital and College.—The Old Students' annual dinner will be held in the Great Hall of the hospital on Tuesday, Oct. 1st, with Sir Frederick Andrewes in the chair.

Dreadnought Hospital, Greenwich.—The Duke and Duchess of York will open the Devonport Pathological Laboratory and the Devonport Nurses' Home at this hospital at 3 P.M. on Monday, July 15th.

Dr. Jessie Macgregor Prize in Medical Science.—The trustees announce the award of this prize, for the triennial period 1929–31, to Miss Helen M. Russell, F.R.C.P. Edin., for her record of work on malaria in the Vasiliki Valley, Macedonia, during 1928. The prize was founded in 1908 as a memorial to the late Dr. Jessie Maclaren Macgregor, of Edinburgh, and is of the value of £75.

A New Edenbridge Hospital.—Since its opening, eight years ago, the Edenbridge and District War Memorial Hospital has been carried on in a converted house which has become unsuitable owing to its structure and its situation on a noisy motor road. It has therefore been decided to erect, at a cost of £20,000, a new building of 20 beds on a three-acre site presented by Mr. T. A. Mason.

Liverpool Ambulance Service.—Hitherto the voluntary hospitals of Liverpool have possessed no ambulances of their own and have been dependent upon those belonging to the police, which are intended only for the conveyance of street casualties. Now, however, an ambulance has been purchased for £1500 by the Liverpool University Guild of Undergraduates out of the proceeds of the recent "Panto. Day," and is about to be presented to the Merseyside Hospitals Council.

International Congress of Dermatology and Syphilology.—The eighth meeting of this congress will be held at Copenhagen from August 5th to 9th of next year. The three principal subjects of discussion will be the Ætiology and Pathogenesis of Eczema; Immunity, Reinfection, and Superinfection in Syphilis; and Tuberculosis of the Skin and Its Treatment. Further particulars may be had from the Secretary-General, Dr. Svend Lomholt, Raadhuspladsen 45, Copenhagen.

International Post-Graduate Courses in Berlin.—Regular courses of post-graduate study are held in Berlin at short intervals, and in addition a number of special courses in various subjects have been arranged for October of this year and for March, 1930. Particulars of these may be had from the Kaiserin Friedrich-Haus, Luisenplatz 2, Berlin, N.W.6, which also provides information about "guest-assistantships" in the clinics, hospitals, and laboratories of the city.

Royal Society of Medicine.—At the annual meeting of Fellows of the Royal Society of Medicine on July 2nd, with Lord Dawson, the President, in the chair, it was stated that the National Fund for the Acquisition of Radium was to be administered under a Royal Charter, which would probably be operative in the autumn. It was also announced that members of the Society resident in Sydney, New South Wales, with other medical men in that city, had made the first application to the Society to be allowed to form a section or branch. After the meeting a demonstration was given of a photostat with which the library has been equipped on the suggestion of Mr. Edwards, the secretary. This will make it possible to send to applicants in the provinces or abroad *exact reproductions* of pages or articles of any books or periodicals, thus fulfilling the circulating requirements without either depleting the library or interfering with its primary function of reference library. The whole process of reproduction occupies less than an hour.

Royal Medico-Psychological Association.—The eighty-eighth annual meeting of this Association will open on Wednesday, July 10th, at the Westminster City Hall, Charing Cross-road, London, W.C., and will continue on Thursday and Friday at the house of the British Medical Association in Tavistock-square. Prof. J. Shaw Bolton will take the chair at the first meeting, and in the afternoon, after a civic welcome by the Mayor of Westminster, the new President, Dr. Nathan Raw, will be inducted to the chair and will deliver an address entitled Fear: A Sociological Study. The Gaskell Medal and Prize for 1929 is to be presented on Thursday to Dr. Alexander Walk. The annual dinner will be held at the Hotel Metropole, Northumberland-avenue, at 7.15 for 7.30 P.M. on the same day. The proceedings on the two subsequent days will include a visit to Springfield Mental Hospital on Thursday afternoon and a discussion on the report of the Mental Deficiency Committee on Friday morning.

Mr. Arthur Greenwood, the Minister of Health, has appointed Mr. Joseph Compton, M.P., to be his Parliamentary Private Secretary.

South Devon and East Cornwall Hospital.—The first section of the extension scheme of this institution, consisting of a new children's ward, has been opened by the Countess of Mount Edgcumbe.

Ulster Hospital for Women and Children.—Last year the number of admissions to the wards, of out-patients, and out-patients' visits constituted a record, the total exceeding by more than 5000 the figures of the preceding year. The average cost per effective bed was £75 6s. 9½*d.*, and the daily cost of in-patients 4*s.* 1½*d.*

Hospital of St. John of Jerusalem.—The following appointments to the Order have been made:—As officers: Dr. K. F. Lund, Dr. R. C. Robertson, Dr. F. N. Kay Menzies, Major S. J. C. Holden, Dr. B. R. Billings, Dr. A. E. Porter, Major W. H. F. Noble, Dr. A. B. McMaster, Dr. A. L. Macleod, Major F. R. Humphreys, Colonel A. H. Tubby, Lieut.-Colonel G. T. Samman, and Dr. E. Burnet. As serving Brothers: Dr. G. Skeen, Captain H. F. J. Norrie, Dr. J. C. Bekitt, Major W. H. Borrie, Dr. J. Graham, Dr. A. Tennyson-Smith, Dr. K. Mackenzie, and Lieut.-Colonel G. E. Peacock.

University of Liverpool Animals' Hospital.—On June 28th Lord Howard de Walden opened a new hospital at the Liverpool University Veterinary School. It is the first animals' hospital to be conducted in this country by a university, and is primarily intended for research and the *instruction of veterinary students. The building funds have* come from subscribers, one of the chief contributors being Lord Howard de Walden, and from the Development Commissioners, through the Ministry of Agriculture, who have offered £16,000 on a pound-for-pound basis. In addition an annual grant of £2850 will be received.

Royal Medical Benevolent Fund.—At a recent meeting of the Committee 30 grants were made amounting to £912. The following are notes on six of the cases helped by grants and annuities:—

Widow, aged 72, of M.R.C.S., whose husband received an annuity from *this Fund during the last years of his life. On his* death his widow had only the old age pension of £26. Voted £36. Her total income is therefore only £62 a year. Further assistance is being sought for this lady.

Widow, aged 80, of M.R.C.S. and L.S.A. The widow is totally blind. She has an income of £77 a year. The Fund voted £36, making a total income of £113, on which the widow and two daughters have to live. One daughter has to give her full time to looking after her mother owing to her infirmities, the other is trying to find work, but, as she is 47 years of age, has been unable to get employment as a clerk.

Widow, aged 75, of M.R.C.S. and L.S.A., has an income of £72 a year. Voted £26.

Daughter, aged 70, of M.R.C.S., with a private income of £20 and old age pension of £26. Voted an annuity of £30, making a total of £76.

Daughter, aged 81, of M.D. No private income, only the old age pension of £26. Voted an annuity of £30, making a total income of £56. This lady lives with her niece, a music teacher, who has to keep and maintain her on the above.

Daughter, aged 73, of M.R.C.S. Has only the old age pension of £26. Granted an annuity of £10, making her total income £66.

Subscriptions and donations should be sent to the hon. treasurer of the Fund at 11, Chandos-street, Cavendish-square, London, W. 1.

British Pharmaceutical Congress.—The British Pharmaceutical Society held its annual congress last week in Dublin, with the coöperation of the Irish Pharmaceutical Society and the Pharmaceutical Society of Northern Ireland. Our Dublin correspondent writes: "The weather was at its best and all who attended the congress had a pleasant week. The congress opened with a stimulating address from the President, Mr. R. R. Bennett, whose subject was the Changing Foundations of Materia Medica. He spoke of the transition from crude drugs to standardised products, and of the gradual replacement of certain natural products by identical substances synthetically produced. Among many other papers one of more than special interest was read by Mr. M. V. Sargent, of Naas, on the Native Materia Medica of Ireland. He drew attention to the luxuriant wild growth in parts of Ireland of medicinal plants such as digitalis, male fern, broom, dandelion, and couch grass, and he suggested that the collection of these plants could be made to pay from the commercial point of view. The social side of the congress was also successful. The banquet, held in the Mansion House, was honoured by the presence of His Excellency the Governor-General of the Irish Free State. A pleasant garden party was given in the beautiful grounds of the Royal Zoological Society of Ireland by the Directors of Messrs. Boileau and Boyd, Ltd., manufacturing chemists."

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

THE NEW PARLIAMENT.

THE new Parliament was opened on Tuesday, July 2nd. Owing to the recent illness of His Majesty The King, it was not thought advisable to submit him to the strain of a State opening, and the ceremony was therefore performed by Royal Commission. The Lords Commissioners were the Lord Chancellor, the Earl of Kintore, Lord Southborough, Archbishop Lord Davidson, and Lord Denman. The King's speech, which was read in the House of Lords by the Lord Chancellor, stated that while His Majesty regretted that it was not possible to address Parliament in person, he thanked Almighty God that he could look forward with confidence to that complete restoration of health for which the prayers of his people throughout the Empire with a sympathy and affection which called forth his deepest gratitude were offered during the months of his long and serious illness. The Government was at present considering the unanimous report of the independent financial experts appointed to draw up proposals for a complete and definitive settlement of the German reparation problem in preparation for a conference of representatives of the Governments concerned. A settlement of this problem would enable the occupying Powers to proceed with the evacuation of the Rhineland. It was the earnest hope of the Government, in coöperation with the Governments of the Dominions of India and of foreign Powers, to ensure an early reduction of armaments throughout the world. Consultations were taking place regarding the signing of the Optional Clause embodied in the statute of the Permanent Court of International Justice. The question of the resumption of diplomatic relations with the Soviet Government of Russia was also being examined. It would be the foremost endeavour of the Government to deal effectively with the continuing evil of unemployment. Schemes were being prepared for the improvement of the means of transport, for the stimulation of the depressed export trades, for the economic development of the overseas Dependencies, for the improvement of the condition of agriculture, for the encouragement of the fishing industry, and for the improvement of the facilities for the marketing of farm and fishery outputs. Measures were being considered in coöperation with the Dominion Governments to provide greater opportunities for overseas migration. Proposals would be submitted to Parliament in due course dealing with the reorganisation of the coal industry, including hours and other factors and the ownership of minerals. Inquiries would be undertaken immediately in order to discover means to coöperate with the iron and steel and cotton industries to improve their position in the markets of the world. Bills would be introduced for amending and consolidating the existing factory legislation and for giving effect to the obligations entered into in Washington in 1919. Legislation would be undertaken to promote an extensive policy of slum clearance and to make further provision for housing in urban and rural areas. The Government had decided that a time had come to investigate the whole field of legislation relating to the sale and supply of intoxicating liquor and commissioners would be appointed for that purpose. A general survey was proceeding of the various National Insurance and Pension schemes. Meanwhile a Bill was being prepared to amend the Widows', Orphans', and Old Age Contributory Pensions Act, 1925, so as to modify the conditions applicable to certain pensions and to make some increase in the classes of persons entitled to them. A measure would be introduced to remedy the situation created by the Trade Disputes and Trade Unions Act, 1927. At the recent General Election an extended franchise placed in the hands of the whole of the people of adult years the grave responsibility for guarding the well-being of the nation as a constitutional democracy, and the Government proposed to institute an examination of the experiences of the election so that the working of the law relating to Parliamentary elections might be brought into conformity with the new conditions.

MANCHESTER BABIES' HOSPITAL.—The annual report shows that last year there were 881 admissions and 316 discharges, and that the mortality was 14·59 per cent. The most numerous cases, amounting to practically one-third of the discharges, were those of chronic dyspepsia; of rickets, which came next, there were 42. Prematurity accounted for the largest number of deaths (12). The number of premature children increases every year; in 1924 it was four, but in 1928 it had risen to 37. It has been decided to immunise against diphtheria all infants whose parents are willing.

Medical News.

UNIVERSITY OF BIRMINGHAM.—At a congregation held on June 29th the following degrees and diplomas were conferred:—

M.D.—W. D. Beck and C. G. Payton.

M.B., Ch.B.—*W. C. Smallwood, †E. G. Abdel-Malek, F. A. d'Abreu, Adele M. Frankland, C. W. Kidson, F. G. Lewis, A. J. Moffett, E. H. Parkinson, H. R. Kalra, Ali Said, Christopher St. Johnston, F. R. Smith, George Steane, K. S. Thom, and Doris I. Wall.

* First class honours. † Second class honours.

Diploma in Dental Surgery.—B. D. Britten.

Application is invited for the Walter Myers travelling scholarship of £300 for research in pathology during the year 1929–30. Particulars will be found in our advertisement columns.

UNIVERSITY OF DURHAM.—At a Convocation held on June 27th the following degrees and diplomas were conferred:—

M.D.

Max Coll, O. C. Dobson, John Hare, A. H. Holmes, F. W. Marshall, P. M. Rivaz, Gladys Stableforth, A. J. Watson, and Reginald Wear.

M.B., B.S.

Sydney Adler, J. C. Arthur, W. F. Cross, Kenneth Daniels, C. E. Goldberg, H. W. T. Hall, Wilfred Hall, John Maddison, H. D. Ord, A. R. D. Pattison, J. K. H. Scott, J. B. Tilley, and Nora Walkinshaw.

B.HY. AND D.P.H.

Katherine M. Cellan-Jones, O. C. Dobson, and A. J. Watson.

UNIVERSITY OF GLASGOW.—At a ceremony of graduation on June 28th the folllowing degrees were conferred:—

M.D.—*J. S. Young, Moses Cohen, and J. C. H. Mackenzie.

* With honours.

QUEEN'S UNIVERSITY, BELFAST.—At recent examinations the following candidates were successful:—

M.D.

*Robert Armstrong, *W. H. Belford, Robert Evans, H. E. Hall, †R. A. G. Hamilton, J. B. Lyle, W. J. M'Cracken, W. A. Scott, and H. A. Warnock.

* With commendation. † Gold medal.

M.Ch.

F. S. Carson.

M.B., B.Ch., B.A.O.

First Class Honours.—W. J. Hamilton, T. B. H. Haslitt.

Second Class Honours.—J. S. Baxter, Hugh Caldwell, Joseph Gray, J. V. Hurford, C. J. Lord, James Montgomery, and D. A. C. Wilson.

Pass.—D. R. Cairns, Mary V. Cox, J. C. Craig, C. T. Denny, Charles Dick, J. M'K. Dundee, Mabel G. Hall, D. B. L. Harris, Margaret L. Irvine, Wilson Johnston, Marcus Killen, J. K. M'Collum, W. C. MacFaul, G. J. M'Gouran, J. A. MacHugh, James M'Master, Eveline M'Mordie, A. H. Montgomery, D. M. Quinn, L. F. Ragbir, J. G. Ryan, Thomas Scott, J. P. Thomson, H. B. C. M. Wallace, and Alexander Woods.

UNIVERSITY OF LEEDS.—At a congregation held on July 1st the degree of Doctor of Science, honoris causa, was conferred on Dr. Thomas Wardrop Griffith, Emeritus Professor of Medicine in the University.

Introducing Dr. Griffith, Prof. Veale spoke of his unbroken and close connexion with the Medical School for 46 years. Appointed professor of anatomy in 1883 at the early age of 26, he had at once brought the School of Anatomy to the front rank, and had identified himself with the interests and development of the Medical School in every direction. The present fine premises were largely due to his efforts, and the University owed him a lasting debt of gratitude for the careful planning and sound construction of this building, which, though now being substantially enlarged, would be a lasting memorial of his efforts. In 1910 Dr. Griffith had become professor of medicine, and as a clinical teacher he had shown the same mastery of style as had distinguished him in anatomical science. As a physician he had added much to the prestige of the school and to medical science. As an authority on cardiology, and more particularly the difficult and recondite problems of cardiac arrhythmia, his fame was surely established by accurate and extensive clinical research. Throughout his career he had been distinguished by a personal integrity of the highest order, and unswerving loyalty to the most honourable traditions and ideals of his profession, and a devotion excelled by none to the school which his scientific attainments had done so much to adorn.

The degree of Doctor of Medicine was conferred on G. R. Baxter.

BRITISH HOMŒOPATHIC CONGRESS.—Prince George and the Lord Mayor of London will welcome the delegates to this congress which is opening at the Connaught Rooms, London, to-day, Friday, July 5th, under the presidency of Dr. Thomas Macklin Dishington. It is stated that some 250 American medical men are attending the congress.

ST. BARTHOLOMEW'S HOSPITAL AND COLLEGE.—The Old Students' annual dinner will be held in the Great Hall of the hospital on Tuesday, Oct. 1st, with Sir Frederick Andrewes in the chair.

DREADNOUGHT HOSPITAL, GREENWICH.—The Duke and Duchess of York will open the Devonport Pathological Laboratory and the Devonport Nurses' Home at this hospital at 3 P.M. on Monday, July 15th.

DR. JESSIE MACGREGOR PRIZE IN MEDICAL SCIENCE.—The trustees announce the award of this prize, for the triennial period 1929-31, to Miss Helen M. Russell, F.R.C.P. Edin., for her record of work on malaria in the Vasiliki Valley, Macedonia, during 1926. The prize was founded in 1908 as a memorial to the late Dr. Jessie Maclaren Macgregor, of Edinburgh, and is of the value of £75.

A NEW EDENBRIDGE HOSPITAL.—Since its opening, eight years ago, the Edenbridge and District War Memorial Hospital has been carried on in a converted house which has become unsuitable owing to its structure and its situation on a noisy motor road. It has therefore been decided to erect, at a cost of £20,000, a new building of 20 beds on a three-acre site presented by Mr. T. A. Mason.

LIVERPOOL AMBULANCE SERVICE.—Hitherto the voluntary hospitals of Liverpool have possessed no ambulances of their own and have been dependent upon those belonging to the police, which are intended only for the conveyance of street casualties. Now, however, an ambulance has been purchased for £1600 by the Liverpool University Guild of Undergraduates out of the proceeds of the recent "Panto. Day," and is about to be presented to the Merseyside Hospitals Council.

INTERNATIONAL CONGRESS OF DERMATOLOGY AND SYPHILOLOGY.—The eighth meeting of this congress will be held at Copenhagen from August 5th to 9th of next year. The three principal subjects of discussion will be the Ætiology and Pathogenesis of Eczema; Immunity, Reinfection, and Superinfection in Syphilis; and Tuberculosis of the Skin and Its Treatment. Further particulars may be had from the Secretary-General, Dr. Svend Lomholt, Raadhuspladsen 45, Copenhagen.

INTERNATIONAL POST-GRADUATE COURSES IN BERLIN.—Regular courses of post-graduate study are held in Berlin at short intervals, and in addition a number of special courses in various subjects have been arranged for October of this year and for March, 1930. Particulars of these may be had from the Kaiserin Friedrich-Haus, Luisenplatz 2, Berlin, N.W.6, which also provides information about "guest-assistantships" in the clinics, hospitals, and laboratories of the city.

ROYAL SOCIETY OF MEDICINE.—At the annual meeting of Fellows of the Royal Society of Medicine on July 2nd, with Lord Dawson, the President, in the chair, it was stated that the National Fund for the Acquisition of Radium was to be administered under a Royal Charter, which would probably be operative in the autumn. It was also announced that members of the Society resident in Sydney, New South Wales, with other medical men in that city, had made the first application to the Society to be allowed to form a section or branch. After the meeting a demonstration was given of a photostat with which the library has been equipped on the suggestion of Mr. Edwards, the secretary. This will make it possible to send to applicants in the provinces or abroad exact reproductions of pages or articles of any books or periodicals, thus fulfilling the circulating requirements without either depleting the library or interfering with its primary function of reference library. The whole process of reproduction occupies less than an hour.

ROYAL MEDICO-PSYCHOLOGICAL ASSOCIATION.—The eighty-eighth annual meeting of this Association will open on Wednesday, July 10th, at the Westminster City Hall, Charing Cross-road, London, W.C., and will continue on Thursday and Friday at the house of the British Medical Association in Tavistock-square. Prof. J. Shaw Bolton will take the chair at the first meeting, and in the afternoon, after a civic welcome by the Mayor of Westminster, the new President, Dr. Nathan Raw, will be inducted to the chair and will deliver an address entitled Fear: A Sociological Study. The Gaskell Medal and Prize for 1929 is to be presented on Thursday to Dr. Alexander Walk. The annual dinner will be held at the Hotel Metropole, Northumberland-avenue, at 7.15 for 7.30 P.M. on the same day. The proceedings on the two subsequent days will include a visit to Springfield Mental Hospital on Thursday afternoon and a discussion on the report of the Mental Deficiency Committee on Friday morning.

Mr. Arthur Greenwood, the Minister of Health, has appointed Mr. Joseph Compton, M.P., to be his Parliamentary Private Secretary.

SOUTH DEVON AND EAST CORNWALL HOSPITAL.—The first section of the extension scheme of this institution, consisting of a new children's ward, has been opened by the Countess of Mount Edgcumbe.

ULSTER HOSPITAL FOR WOMEN AND CHILDREN.—Last year the number of admissions to the wards, of out-patients, and out-patients' visits constituted a record, the total exceeding by more than 5000 the figures of the preceding year. The average cost per effective bed was £75 6s. 9½*d.*, and the daily cost of in-patients 4*s.* 1½*d.*

HOSPITAL OF ST. JOHN OF JERUSALEM.—The following appointments to the Order have been made:—As officers: Dr. K. P. Lund, Dr. R. C. Robertson, Dr. F. N. Kay Menzies, Major S. J. C. Holden, Dr. B. R. Billings, Dr. A. E. Porter, Major W. H. F. Noble, Dr. A. B. McMaster, Dr. A. L. Macleod, Major F. R. Humphreys, Colonel A. H. Tubby, Lieut.-Colonel C. T. Samman, and Dr. E. Burnet. As serving Brothers: Dr. G. Skeen, Captain H. F. J. Norrie, Dr. J. C. Bekitt, Major W. H. Horrie, Dr. J. Graham, Dr. A. Tennyson-Smith, Dr. K. Mackenzie, and Lieut.-Colonel G. E. Peacock.

UNIVERSITY OF LIVERPOOL ANIMALS' HOSPITAL.—On June 28th Lord Howard de Walden opened a new hospital at the Liverpool University Veterinary School. It is the first animals' hospital to be conducted in this country by a university, and is primarily intended for research and the instruction of veterinary students. The building funds have come from subscribers, one of the chief contributors being Lord Howard de Walden, and from the Development Commissioners, through the Ministry of Agriculture, who have offered £15,000 on a pound-for-pound basis. In addition an annual grant of £2850 will be received.

ROYAL MEDICAL BENEVOLENT FUND.—At a recent meeting of the Committee 30 grants were made amounting to £912. The following are notes on six of the cases helped by grants and annuities:—

Widow, aged 72, of M.R.C.S., whose husband received an annuity from this Fund during the last years of his life. On his death his widow had only the old age pension of £26. Voted £36. Her total income is therefore only £62 a year. Further assistance is being sought for this lady.

Widow, aged 80, of M.R.C.S. and L.S.A. The widow is totally blind. She has an income of £77 a year. The Fund voted £36, making a total income of £113, on which the widow and two daughters have to live. One daughter has to give her full time to looking after her mother owing to her infirmities, the other is trying to find work, but, as she is 47 years of age, has been unable to get employment as a clerk.

Widow, aged 75, of M.R.C.S. and L.S.A., has an income of £72 a year. Voted £26.

Daughter, aged 70, of M.R.C.S., with a private income of £20 and old age pension of £26. Voted an annuity of £30, making a total of £76.

Daughter, aged 84, of M.D. No private income, only the old age pension of £26. Voted an annuity of £30, making a total income of £56. This lady lives with her niece, a music teacher, who has to keep and maintain her on the above.

Daughter, aged 73, of M.R.C.S. Has only the old age pension of £26. Granted an annuity of £40, making her total income £66.

Subscriptions and donations should be sent to the hon. treasurer of the Fund at 11, Chandos-street, Cavendish-square, London, W. 1.

BRITISH PHARMACEUTICAL CONGRESS.—The British Pharmaceutical Society held its annual congress last week in Dublin, with the coöperation of the Irish Pharmaceutical Society and the Pharmaceutical Society of Northern Ireland. Our Dublin correspondent writes: "The weather was at its best and all who attended the congress had a pleasant week. The congress opened with a stimulating address from the President, Mr. R. R. Bennett, whose subject was the Changing Foundations of Materia Medica. He spoke of the transition from crude drugs to standardised products, and of the gradual replacement of certain natural products by identical substances synthetically produced. Among many other papers one of more than special interest was read by Mr. M. V. Sargent, of Naas, on the Native Materia Medica of Ireland. He drew attention to the luxuriant wild growth in parts of Ireland of medicinal plants such as digitalis, male fern, broom, dandelion, and couch grass, and he suggested that the collection of these plants could be made to pay from the commercial point of view. The social side of the congress was also successful. The banquet, held in the Mansion House, was honoured by the presence of His Excellency the Governor-General of the Irish Free State. A pleasant garden party was given in the beautiful of the Royal Zoological Society of Ireland by the Direct of Messrs. Boileau and Boyd, Ltd., manufacturing

ASSOCIATION OF SURGEONS' SCHOLARSHIP.—The Association of Surgeons of Great Britain and Ireland invites applications for a surgical scholarship of £350 to be held for one year while the holder pursues some definite line of research or study. Further particulars will be found in our advertisement columns.

ROYAL DUNDEE INSTITUTION FOR THE BLIND.—At the annual meeting of this Institution it was stated that the number of blind employees was now 108, compared with 87 in 1920. The blind workers could not produce enough to enable the directors to make a profit, and therefore the increase in workers meant an increase in the anual deficit. Although the increase in goods sold was £1100, there was a net loss on the industrial account of £735 as compared with £496 last year. The general charity account showed a deficit of £2144 compared with last year's £2245.

HOSPITALS AND MOTORISTS.—Under this title the *Manchester Guardian* on June 29th published a selection of the results of a questionaire sent to voluntary hospital authorities for the purpose of discovering whether the problem of payment for treatment in motor accidents is as acute as some recent hospital reports have suggested. "The answers show," it is stated, "that many institutions are suffering a heavy financial strain; that very few of the patients contribute anything to the cost of their treatment; and that most hospital authorities agree on the necessity for some plan whereby payment should be assured." At the Manchester Royal Infirmary 140 in-patients were received, who spent 2708 days in hospital at a cost to the infirmary of £1196, and the patients' contributions amounted to £152. At Ancoats Hospital the cost to the hospital was £320 and £12 was received as patients' contributions. At the Manchester Victoria Jewish Hospital the cost was estimated at £450 and the cash received in return at only £50. At Oldham Infirmary during 1928 187 patients were treated at a cost of approximately £800 and "the sum received in respect of these patients was negligible." At the Royal Infirmary, Bradford (Yorks), 137 in-patients (who remained 2929 days in hospital) and 229 out-patients were treated at a total cost of £1174 and about £24 was received as contributions from the in-patients. At the Royal Infirmary, Derby, 100 victims of motor accidents were admitted during the year ended May 31st last, the average number of beds occupied during this period being 14. In addition there were a large number of out-patients treated. The cost of treating the in-patients was £1799 and the total contributions received towards their maintenance was £84 8*s*. At Warrington Infirmary £735 was expended in in-patient treatment alone last year and towards this the patients contributed £89. At Leeds General Infirmary 1135 motor accident cases were received. They cost the institution £4307 and towards that sum contributed £167. Much the same replies were received from hospitals at Blackpool, Sunderland, Bury, and other towns to the questionaire of the *Manchester Guardian*.

Medical Diary.

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

FRIDAY, July 12th.—8.30 P.M., Continuation of Discussion on Colonel L. W. Harrison's Paper, Review of Experimental Work in Syphilis and its Possible Bearing on Man.

SOCIETY FOR THE STUDY OF INEBRIETY, 19, Park-crescent, Portland-place, W.
TUESDAY, July 9th.—4 P.M., Mr. W. McAdam Eccles: Some Gaps in the Study of Inebriety (Presidential Address), followed by a discussion on the Toxic Effects of Methylated Spirits and Impure Forms of Alcohol, to be opened by Sir William Willcox.

ROYAL MEDICO-PSYCHOLOGICAL ASSOCIATION.
WEDNESDAY, July 10th.—(At the Westminster City Hall, Charing Cross-road, W.C.), Annual Meeting.
THURSDAY and FRIDAY.—(At the B.M.A. House, Tavistock-square), Annual Meeting continued.

ROYAL SANITARY INSTITUTE.
SATURDAY, July 13th.—Annual Congress opens at Sheffield.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, London, W.
MONDAY, July 8th, to SATURDAY, July 13th.—ROYAL NATIONAL ORTHOPÆDIC HOSPITAL, 234, Gt. Portland-street, W. Mond. 1.30 to 2.30 P.M., Demonstration by Mr. Laming Evans. 2.30 to 4 P.M., in In-patients and Out-patients Depts. No fee.—LONDON LOCK HOSPITAL, 91, Dean-street, Oxford-street, W. Tues., 3 P.M., Clinical Demonstration by Major Corbett. No fee.—HOSPITAL FOR DISEASES OF THE SKIN, Blackfriars-road, S.E. Afternoon course consisting of instruction in Out-patient Dept. Special case demonstrations on Tues. Further particulars from the Fellowship of Medicine.

NORTH-EAST LONDON POST-GRADUATE COLLEGE: Prince of Wales's General Hospital, Tottenham, N.
MONDAY, July 8th.—2.30 to 5 P.M., Medical, Surgical and Gynæcological Clinics. Operations.
TUESDAY.—2.30 to 5 P.M., Medical, Surgical, Ear, Nose and Throat Clinics. Operations.
WEDNESDAY.—2.30 to 5 P.M., Medical, Skin, and Eye Clinics. Operations.
THURSDAY.—11.30 A.M., Dental Clinics. 2.30 to 5 P.M., Medical, Surgical, Nose, Throat and Ear Clinics. Operations.
FRIDAY.—10.30 A.M., Throat, Nose and Ear Clinics. 2.30 to 5 P.M., Surgical, Medical, and Children's Diseases Clinics. Operations.

EAST LONDON HOSPITAL FOR CHILDREN, Shadwell, E.
WEDNESDAY, July 10th.—4 P.M., Mr. K. J. Acton-Davis: The Surgical Treatment of Rickets, with Illustrative Cases.

ST. PAUL'S HOSPITAL, Endell-street, W.C.
THURSDAY, July 11th.—4.30 P.M., Mr. Claude Mills: Some Interesting Urological Cases with Demonstrations of Pathological Specimens and Radiograms of Same.

Appointments.

GRIFFITHS, J. I., M.B., B.S. Lond., has been appointed Third Asst. M.O. to the Hammersmith Board of Guardians.

MACGLASSON, J., M.B., Ch.B. Edin., Parochial Medical Officer and Vaccinator, Canonbie.

THOMSON, O. S., M.D., Ch.B. Glasg. D.P.H., Part-time Lecturer in Public Health Administration in the University of Belfast.

Certifying Surgeons under the Factory and Workshop Acts: GOODWIN, A. C., M.B., B.Ch. Oxf. (Newport, Isle of Wight); NELSON, H. P., M.B., B.S. Durh. (Brampton, Cumberland); O'SHEA, J. J. M.B., B.Ch. R.U.I. (Chipping Norton); and PRESTON, F., L.R.C.P. Lond., M.R.C.S. (Norwich).

Vacancies.

For further information refer to the advertisement columns.

Association of Surgeons of Great Britain and Ireland.—Surgical Scholarship. £350.
Birmingham and Midland Homœopathic Hospital and Dispensary, Easy-row.—H.S. £150.
Birmingham, Selly Oak Hospital.—Cas. O. At rate of £200.
Birmingham City Mental Deficiency Institution, Coleshill Hall.—Med. Supt. £700.
Birmingham University.—Walter Myers Travelling Studentship £300.
Bombay Goculdas Tejpal Hospital.—Hon. Surgeon.
Brighton, Royal Sussex County Hospital.—H.S. £150.
Bristol Royal Infirmary.—Sen. Res. M.O. £200. Also Res. H.S.'s. to Special Departments. At rate of £60. Res. Cas. H.S. and Dental H.S. At rate of £80 each.
Burton-on-Trent General Infirmary.—H.S. £150.
Buxton, Devonshire Hospital.—Asst. H.P. At rate of £150.
Cardiff, Welsh National School of Medicine.—Jun. Asst. in Med. Unit. £500. Jun. Asst. in Surg. Unit. £350. Also Asst. Lecturer in Pathology. £500.
Cardiff Royal Infirmary.—Four H.S.'s and three H.P.'S. Each at rate of £50.
Chester Royal Infirmary.—H.S. and Cas. O. £120.
City of London Hospital for Diseases of the Heart and Lungs, Victoria Park, E.—Asst. Laryngologist.
Colne Borough.—M.O.H., &c. £800.
Dreadnought Hospital, Greenwich.—Asst. Radiologist. 50 gns.
Durham County Hospital.—Jun. H.S. At rate of £120.
Exeter, Royal Devon and Exeter Hospital.—Asst. H.S. At rate of £100.
Exminster, Devon Mental Hospital.—Jun. Asst. M.O. £300.
Glasgow, Hawkhead Asylum.—Asst. M.O. £275.
Gloucestershire Royal Infirmary, &c.—Second H.S. At rate of £100.
Great Yarmouth General Hospital.—Jun. H.S. £100.
Hospital for Consumption, &c., Brompton, S.W.—H.P. At rate of £50.
Hull Maternity Home and Infants' Hospital, Hedon-road.—Res. M.O. £450.
Ilford Emergency Hospital.—Sen. and Jun. H.S.'s. £110 and £100 respectively.
Ipswich, East Suffolk and Ipswich Hospital.—H.S. At rate of £120.
Jewish Maternity Hospital, Underwood-street, E.—Res. M.O. At rate of £50.
Liverpool Open-Air Hospital for Children, Leasowe.—Jun. Res. M.O. At rate of £200.
Lowestoft and North Suffolk Hospital.—H.S. £120.
Macclesfield General Infirmary.—Res. H.S. £180.
Maidstone, West Kent General Hospital.—Hon. Anæsthetist.
Manchester, Ancoats Hospital.—Res. M.O. £150.

Manchester, St. Mary's Hospitals.—Four H.S.'s. Each at rate of £50.
Marseilles, Queen Alexandra Memorial Hospital.—Res. M.O. At rate of £150.
Middlesex County Council.—Tuberculosis M.O. £750.
National Hospital, Queen-square, W.C.—Pathologist. £200.
Newcastle-upon-Tyne, City Hospital for Infectious Diseases.—Res. Med. Asst. £350.
Nigeria, West African Medical Staff.—Pathologists. Each £500.
Nottingham General Hospital.—Two H.S.'s for Special Depts. Each at rate of £150.
Oswestry, Shropshire Orthopaedic Hospital.—H.S. £200.
Plaistow Fever Hospital, E.—Second Asst. M.O. £300.
Preston and County of Lancaster, Queen Victoria Royal Infirmary.—H.P. £150.
Prince of Wales's General Hospital, Tottenham, N.—Hon. Asst. P.
Princess Louise Kensington Hospital for Children, North Kensington.—Hon. Radiologist.
Rhondda U.D.C.—Asst. M.O.H., &c. £600.
Romford Isolation Hospital, Rush Green.—Med. Supt. £750.
Rotherham Hospital.—Sen. H.S. £200.
Royal Army Medical Corps.—25 Commissions.
Royal Waterloo Hospital for Children and Women, Waterloo-road, S.E.—Cas. O. £150.
St. Albans, Napsbury Mental Hospital.—Jun. Asst. M.O. £185.
St. John's Hospital, Lewisham, S.E.—Two Res. House Appts. Each at rate of £100.
St. Leonards-on-Sea, Buchanan Hospital.—Locum Tenens H.S. At rate of £250.
St. Mary's Hospital for Women and Children, Plaistow, E.—Clinical Asst.
Sheffield Children's Hospital.—Jun. H.S. £100.
Sheffield Royal Hospital.—Res. Ophth. H.S. At rate of £50.
Sheffield Royal Infirmary.—Surg. Reg. £200. Also Asst. Cas. O. H.S., Ophth. H.S., and Asst. Ophth. H.S. Each at rate of £80.
Sleaford, Kesteven Mental Hospital.—Med. Supt. £700.
South Africa, Bloemfontein Hospital.—Sister for X Ray and Electrical Dept. £100.
Stafford, Staffordshire General Infirmary.—H.S. At rate of £200.
Stoke-on-Trent, North Staffordshire Royal Infirmary.—H.S. £160. Also H.S. to Ophthalmic and Aural Depts. At rate of £150.
Swansea Hospital.—H.S. £150.
Tunbridge Wells and Counties General Hospital.—H.S. £160.
West End Hospital for Nervous Diseases, Gloucester Gate, Regent's Park, N.W.—Jun. H.P. At rate of £100.
West London Hospital, Hammersmith, W.—Aural and Ophth. H.S. and Res. Asst. Cas. O. At rate of £100. Also Res. Anæs. At rate of £100.
Willesden General Hospital, N.W.—Refraction Assistant. 50 gns.
Winchester, Royal Hampshire County Hospital.—Res. H.S. £150.
Woolwich and District War Memorial Hospital, Shooters-hill, S.E.—H.P. and H.S. Each at rate of £125.
The Chief Inspector of Factories announces vacancies for Certifying Factory Surgeons at Callington (Cornwall) and at Felixstowe (Suffolk).

Births, Marriages, and Deaths.

BIRTHS.

BUTLER.—On June 25th, to Florence (*née* Jordan), the wife of Dr. M. F. Butler, of Beckenham-road, Beckenham, of a daughter.

HILLMAN.—On June 28th, at Bentinck-street, W., the wife of Oscar Stanley Hillman, M.B., F.R.C.S., Wilson-grove, Southsea, of a daughter.

SHAW.—On June 22nd, at a nursing home in London, the wife of Dr. F. R. S. Shaw, M.B., M.C., Tuz Khurmatu, Iraq, of a son.

THOMSON.—On June 28th, at Lavington, Barnet, Herts, the wife of Dr. N. Gray Thomson, of a daughter.

MARRIAGES.

FRANCE—CORKERY.—On June 26th, at St. Augustine's, London, Robert Scoular France, M.B., Ch.B., to Marjorie Griffin Courtenay, daughter of the late Colonel W. A. Corkery, Indian Medical Service, and of Mrs. Corkery, Ael-y-Bryn, Merthyr Vale, Glamorgan.

DEATHS.

HENDERSON.—On June 23rd, at Allister Cottage, Inverness, Lieut.-Colonel George Henderson, M.D., F.L.S., F.R.G.S., late I.M.S. (H.E.I.C.S.), in his 93rd year.

LEAPINGWELL.—On June 25th, Edward Jodrell Leapingwell, M.B., of Apsley Guise, aged 80 years.

MOXHAM.—On June 27th, at Aldborough, Marcus Camplin Moxham, M.R.C.S., L.R.C.P., L.S.A.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Comments, and Abstracts.

DISEASES OF THE JEWS.

IN opening a symposium on Some Diseases of the Jewish Race at the London Jewish Hospital Medical Society on June 13th, with Dr. A. GOODMAN LEVY in the chair, Sir HUMPHRY ROLLESTON said that diseases had been described as racial diseases of the Jews for no better reason than that the first recorded cases happened to have occurred among Jews. Such was the case with the condition known as dystonia musculorum deformans, or Oppenheim's disease. But there were diseases which if they did not appear exclusively among Jews were said to occur more frequently among them—e.g., thrombo-angiitis obliterans. It had recently been suggested that this disease was on the decrease among Jews and on the increase among Gentiles, and it was possible that the stress laid in the past on the racial nature of this affection had led to its being overlooked when it occurred among Gentiles. According to Telford and Stopford the alleged racial character of this disease was the result of a "topographical" accident. It was said by some that its course in Jews was earlier and more severe than in Gentiles, but the opposite view had also been advanced. On the question of amaurotic familial idiocy it must be pointed out that there was a series of allied conditions of which amaurotic familial idiocy and retinitis pigmentosa were the extremes, the first occurring early in life among Jews and the latter coming on much later in the case of both Jews and non-Jews. Both obesity and diabetes were relatively common in Jews, and it had been suggested by Joslin that Jews got diabetes because they were fat, and they were fat because of dietetic excess. But it must be remembered that Gaucher's and Niemann's diseases, which were disturbances of fat metabolism, were probably more frequent among Jews. Acromegaly had also been said to be more common among Jews, and anterior lobe pituitarism as a feature of the Jewish race was compatible with Keith's contention that the special effects of pituitary activity were best seen in the Caucasian type. That Gaucher's disease was regarded as being specially common among Jews was probably due to the accident that it had been extensively investigated at the Mount Sinai Hospital. Niemann's disease, which was probably a more severe type of Gaucher's disease, seemed to be more frequent among Jews—if one could argue from the 15 cases reported. It probably exemplified the rule suggested by the relationship of amaurotic familial idiocy and retinitis pigmentosa—namely, that in the Jewish race there was a constitutional factor which determined an earlier onset and a more severe form of certain diseases. On the incidence of cancer, the recent work of Sourasky had shown that whilst the total cancer mortality among Jews corresponded fairly with that of the countries in which they resided, there were some differences in the distribution of these growths, but that these differences were probably due to the mode of life led by Jews rather than to a racial factor. There appeared to be a definite resistance to tuberculous infection among Jews, which was perhaps to be explained partly by the infrequency of alcoholism among them.

Mr. A. H. LEVY pointed out that it was wrong to regard amaurotic familial idiocy as a specifically Jewish disease. Juvenile and adolescent cerebro-macular degeneration were generally looked on as being allied to amaurotic familial idiocy, but in his opinion were not at all allied. Mr. Levy touched on the question of the alleged greater frequency of glaucoma among Jews, which he could not substantiate from his experience, and on the incidence of cataract, which was probably not disappearing so rapidly among Jews as it seemed to be doing in the general population.

Cancer and Tubercle.

Mr. M. SOURASKY said that the fact which emerged from a recent investigation was that Jews as a race were neither immune from cancer nor specially prone to it. The statistics of six European capitals with large Jewish populations had been scrutinised, and in each of them the incidence of cancer among Jews followed closely that obtaining among their neighbours. On the whole there was a closer relationship between the Jews and non-Jews of any particular city than between the Jews of different cities. But apparently Jews had a definitely different incidence of cancer of the various organs from that of their neighbours.

Among Jews cancer of the generative organs and of the mouth seemed to be less common and that of the gastro-intestinal tract more so than among non-Jews. There were, however, established ætiological factors operating in the Jewish community capable of explaining these differences without assuming the operation of a problematic racial factor—immunity or predisposition, as the case might be. Thus the well-known association of cancer of the tongue with chronic inflammation of this organ, which was so often of syphilitic origin, adequately explained the low incidence of cancer of the tongue in Jews, as syphilis was decidedly less common—and was still less common in the past—among them than among non-Jews. Not a single case of penile cancer had been recorded for Jews, whilst the disease accounted for about 1 to 2 per cent. of all cancer deaths among non-Jewish men. As for cancer of the breast, the incidence in Jewish women varied in different cities, being sometimes lower, sometimes a little higher than that for the rest of the population. In London the incidence among the poor Jews was lower than that among the wealthy. It was pointed out that among the richer Jews there were more unmarried women, the marriages were later, and the birth-rate was lower, all factors held to favour breast cancer. The remarkably low incidence of uterine cancer (one-third to one-half the number occurring in the rest of the population) might be attributable to the observance of the Mosaic system of hygiene, and it was of interest to note that this form of cancer appeared to be increasing in the Jewish community.

Dr. J. Burnford remarked upon the extreme rarity of any specifically racial diseases, whether of Jews or of other races. The topography of disease was not so much a question of racial predisposition and immunity as one of environment. Theoretically speaking there was a better case for racial immunity than for predisposition. Natural selection was more likely to produce a group of people resistant to certain affections than one which was specially prone to particular diseases, and racial diseases had a way of evaporating into thin air when they were carefully investigated. It was generally assumed that diabetes was very common amongst Jews; in the speaker's experience this had not been very noticeable.

Dr. W. M. Feldman said that the mortality-rate from tuberculosis was lower among Jews than among Gentiles, which was to be explained by the fact that the disease was less fatal among them. This could be seen from the greater number of Jews who responded favourably to treatment. In Dr. Feldman's opinion the explanation was probably that Jews acquired immunity from frequent exposure during childhood to mild doses of tuberculosis, being especially prone to this on account of the greater frequency of the disease among Jews, its milder character, and the greater degree of overcrowding. The greater care Jews bestowed on their infants and their greater sobriety probably also counted. The absence of drunkenness among Jews might be due to the fact that Jews usually took some food with their drink (thus unintentionally delaying the absorption of alcohol into the blood) and by the deterrent effect of public opinion, which in Jewish communities ostracised the drunken.

Eyesight.

Mr. A. Sourasky said that in a recent investigation 1040 Jewish boys were examined as regards eyesight in a group of Jewish evening schools in the East End of London, and 600 non-Jewish boys in London County Council schools in the same district. The tests showed that the percentage of Jewish boys with visual defect was 43·2 as against only 21·7 of the non-Jewish. The conclusion often drawn from this, that the extra hours of evening study in Jewish classes were responsible for this grievous condition, was unjustified. Children at the age of 5 and 6 who had not yet reached school age, and therefore could not be influenced by school-life, showed a similar amount of visual defect to that found at the school-leaving age, between 12 and 14. It was found on an investigation of defects seen among 516 Jewish and 892 non-Jewish children that the proportion of long-sighted and short-sighted was such as to suggest that among Jewish children short sight was twice as frequent as among non-Jewish. At the same time the tests led to the detection of very striking differences in the kind of long-sight observed among Jewish children. One type, "low hypermetropia," was found to be more common in Jewish children than the other forms of long sight, and this was not the case with non-Jewish children. The predisposition to short sight in Jewish children and the greater incidence among Jews would appear to be the concomitant of the fact that the anthropological characteristics of the eyes of Jews were such as to leave little margin between the normal and the myopic. Hence slight disturbances were more likely to result in myopia in Jewish children than in the non-Jewish.

Dr. J. Brander remarked on the earlier onset of dementia præcox among Jews.

In the subsequent discussion Dr. F. Parkes Weber said that in his opinion thrombo-angiitis obliterans was a disease with an economic basis rather than a racial one. Dr. Bernard Myers held that many Jewish characteristics could be explained on the basis of endocrine disturbances.

Dr. D. Nabarro and Dr. N. Pines spoke on arteriosclerosis and Dr. H. Gainsborough on the infrequency of syphilis in the older Jews.

A vote of thanks to Sir Humphry Rolleston was moved by Dr. L. Mandel.

BOOKS ON CHILD CARE.

The issue in all countries of numerous books on the care of infants and children is an interesting sign that mothers, and not only educated mothers, are abandoning tradition alone as a guide to nurture and are seeking help from science. A manifestation of this spirit in this country is the popularity of Baby Week, now being held in London for the thirteenth successive year. Reports of conferences and lectures stimulate women concerned with the rearing of children to seek further information and advice on choice of popular books is often sought from the family doctor. Among those produced recently three written by medical men deserve attention. "The Care of the Child," by Dr. Alton Goldbloom (New York: Longmans, Green and Co. Pp. 240. $1.50) is designed especially to act as a guide to perplexed mothers, and to provide them with up-to-date knowledge on the feeding and management of small children. In selecting the points to be discussed the author has been guided by the questions which have most frequently been put to him in the past. The normal limits of growth, development, and activity are well defined, and all that advice which deals with nursing and general management is admirable. The section on artificial feeding is rather more open to criticism. The statement appears that "the group of dried milks, and unsweetened condensed milks, are quite as satisfactory as ordinary milk"; those who do not believe this to be true would prefer that the perplexed mother should not see it set out so dogmatically. The chapter on diets of older children is a particularly useful one, a clear idea being given not only of the articles of food which are suitable, but of the quantities. "The Essentials of Infant Feeding" is the title of an excellent little book by Dr. E. A. Barton, of which a second edition has now appeared. (London: H. K. Lewis. Pp. 79. 3*s.* 6*d.*) This book provides an admirably clear introduction to the subject of infant feeding which would not be beyond the grasp of the educated mother, though it is adequate for the medical student. The teaching is well up to date. In the second edition complementary replaces supplementary feeding as the method of choice in mixed feeding, and recent views on vitamins have been included. "The Child's Diet" (H. K. Lewis. 3*s.*) is also a book which may safely be put in the hands of parents. This little book was originally designed by Dr. J. Sadler Curgenven for the use of his own patients and has now reached its third edition. It deals with the feeding of normal infants and children, and with diet in a few common nutritional disorders. It is written simply, and conveys throughout the impression of the writer's extensive practical experience. For the artificial feeding of infants comparatively simple dilutions are recommended; the actual details of preparation of the mixtures are not very clearly explained. The chapter on the feeding of older children is perhaps the best part of the book, and the closing chapter containing nursery recipes should also be of great assistance to mothers.

Rather more elementary in treatment are two little books, by Mrs. J. Langton Hewer, which have achieved great popularity. One, which is hardly more than a pamphlet, "The Baby of To-day" (Bristol: John Wright and Sons. Pp. 32. 4*d.*) is intended for those beginning to study creche work, girl guides, and the like, and provides sound teaching in concise form on the essentials of baby management, mental and physical. Rather surprisingly, long clothes are still recommended for the young baby, and the sample tables of food suggest that a child of 18 months should have none but minced meat, though the value of hard, crusty food is emphasised. The longer book, of 186 pages, entitled "Our Baby," and issued at 2*s.* 6*d.* by the same publishers, first appeared in 1891, and this year reached its nineteenth edition. It is addressed to mothers and nurses, and has for some ten years past served as the standard text-book for students taking the advanced examinations of the National Association for the Prevention of Infant Mortality. "Our Baby" is essentially a text-book, its 186 pages covering the ground connected with pregnancy, and such varied aspects of infant hygiene and care as feeding (natural and artificial), clothing, exercise and sleep, nursery life, and mental and moral training. Further chapters give an outline of minor troubles and ailments, accidents, and illnesses to which the young child is prone, with a section on nursery remedies and a final chapter on "Baby in the Tropics." The paramount importance of fresh air in the nursery is emphasised throughout the book, and also the fact that draughts may often be abolished by opening the window wider as easily as by shutting it. Dietitians will not all endorse the teaching that pasteurisation of milk does not kill disease germs and is not to be recommended. The book contains an immense amount of sane instruction and, with its 36 illustrations and numerous headings, presents an attractive appearance. Finally we may mention "A Handbook for Mothers," by C. Phyllis Armitage. (London: John Bale, Sons and Danielsson. Pp. 124. 2*s.*). The first three sections of this little book, devoted respectively to "Pregnancy," "The Infant" and "The Child," are characterised by optimism born of common sense. The author is at pains to impress upon the mother the strong probability that she and her baby are normal, average people, and that good health and moderate progress, though less interesting to the neighbours than sensational excursions, are matters for pride and not for regret. At the same time, individuality must be allowed for, and a mother must be prepared, on occasion, to supersede an ideal theory by an intelligent sense of proportion, and not to suffer undue heart-burnings if the baby next door sleeps longer or gains weight more rapidly than her own. The book is designed especially for use by mothers who may be far from medical help, and Parts IV. and V., dealing with "Ailments of Infancy and Childhood" and "Infectious Diseases" include directions as to the use of certain drugs and forms of treatment unusual in a volume of this nature. A few of these instructions tend to be somewhat dogmatic. But, on the whole, the advice offered is thoroughly sound. A short appendix describes the use of some simple antiseptics and gives directions for first-aid and for the application of fomentations and enemata, together with a few useful recipes. The handbook is to be commended, as Dr. Quin Lennane, medical officer of health of Battersea, says in his foreword, for its "conciseness, simplicity of language, and avoidance of technical nomenclature."

A TUBERCLE-FREE HERD.

ADDRESSING a party of visitors to the Edinburgh Corporation dairy farm at Colinton Mains, Mr. A. Gofton, Chief Veterinary Officer for Edinburgh, lately gave a valuable account of the steps which have been taken there to secure that the cattle shall be free from tuberculosis.

He explained that the herd which had been formed under his regulation at Colinton Mains existed for one purpose only—namely, to supply milk of the best quality to the children in the City Infectious Disease Hospital. Up to a certain point the Corporation had run the herd on the usual stall-fed principle, and it took a great deal of persuasion before it was ultimately decided to embark on the policy of tubercle-free herd, with all the equipment necessary for producing milk of the best quality. When the decision to change over was reached two questions had to be considered. The first was the provision of the basal stock of tubercle-free cows, and the other was the alteration of the buildings to get the abundance of light and fresh air necessary for maintaining the health of the herd. At the change-over they ceased to buy cows in the ordinary way in the open market. At that time they had 27 head of cattle which were subjected to the tuberculin test, and of these 18 were positive and 9 negative. The 18 were removed from the herd and were disposed of for slaughter as soon as possible. The remaining nine were put into one byre, and the new purchases were put into another byre, the nine non-reactors being sold when they became dry.

The stock at the present time, said Mr. Gofton, consisted of 82 cows. Beginning in the spring of last year they bought as far as they could from tubercle-free herds. They then got heifers which had been grazing out in the open all their days, and never housed, and they had those which were selected tested. That principle proved to be sound, because they had found on subsequent tests that those young heifers had stood up to the test. In building up their herd they had to avoid the introduction of contagious abortion, and therefore, at a very early stage, they subjected all the cows to a blood test for evidence of this infection. They found two, which were at once segregated, and were disposed of where they would be able to do no harm. Further tests were now being made, and he was hoping to be able to say that this troublesome disease had now been eliminated.

Their aim had been to establish an Ayrshire herd, and it was vital that they should breed their own stock and replenish the herd by heifers of their own breeding. They were retaining only the Ayrshire calves, and ultimately these would take the place of the few Friesian, cross, and shorthorn cows that were in the herd. The 65 cows in milk in all stages of lactation were yielding 170 gallons of milk, or an average of 2½ per cow per day. Official recording was begun in the beginning of this year and since then 40 cows had been officially recorded, giving an average of 4 per cent. butter fat. Their output to the hospital was almost 152 gallons per day, the reminder of the total production of 170 gallons going to the workers and for calf-feeding.

Mr. Gofton's account of this farm deserves careful study, for it is important that milk supplied to an infectious disease hospital should be free from tuberculous infection, to which children suffering from scarlet fever, measles, and the other exanthems are especially susceptible. Colinton Hospital includes beds and shelters for cases of non-pulmonary tuberculosis, and it would obviously be absurd to provide these with milk which was likely to be infected.

MENTAL HANDICAPS IN LITERATURE.

A BOOK purporting to deal with some of the medico-psychological influences which tend to modify or handicap individuals in their literary efforts should find eager readers. One of the well known Mental Handicap series,[1] attractively written by Dr. E. M. Cox, is devoted to this subject, and will be welcomed by those who have a taste for inquiry into the medical histories of great writers. The book is divided into eight chapters, of which as many as five are devoted to heredity, alcohol and other narcotics, poverty and affluence, the effect of epochal conditions, and toxæmic conditions. These headings suggest physiological rather than mental handicaps, though it is obviously true that such factors must influence the minds of writers. The author cites Poe and Chatterton as furnishing striking examples of the influence of heredity and environment on literary work and output, and it is true that both men came of neurotic stock. But it is at least probable that but for this stock neither might have written anything above the level of mediocrity. Of the opium-takers, Shelley, Coleridge, De Quincey, Francis Thompson, and Poe are quoted as having consumed narcotics, mostly opium, with profound results upon their works, both in quality and quantity. Coleridge died at the age of 62, and at one time he is said to have consumed two quarts of laudanum a day. Dr. Cox raises the interesting question as to whether the laudanum of the early nineteenth century had as great an alkaloid content as that of the present day.

The chapter on the effect of epochal conditions is one of the best in the book. The author has some happy hits at the literary tendencies of the modernist school. In them, he says, "we find violence exploited to the limits of mental endurance, and, in what is called poetry, we find crudity in expression, distortion in imagination, and often a distressing ignorance of the real value of words, their origins, their significance, and their use." Dr. Cox ascribes these tendencies in part to the ten-year failure to control adolescence after 1914, and believes that much of this violence will subside, and that a recognition of literary culture *as something more than a mere defiance of tradition* must take place. Of modern psychological views there is little to be found in these pages. Beyond a brief reference to the "inferiority complex," and "neurasthenia," there is no attempt to make more than a superficial analysis of mental handicaps. After all, the reasons for a man being a literary genius and an alcoholic may be the same. The fierce repressive paternal influence in the childhood of the Brontës had more to do with their gloomy brilliance than had any physiological factor. The author himself agrees that the presence of a neurotic strain in the character may itself produce a special intellectual development, and lay the foundation of success in literary work. This view promises more psychology and less physiology, a promise which is not fulfilled; but the little book is likely to stimulate the interest of a wide circle of readers.

BROWN *v.* WHITE BREAD.

To the Editor of THE LANCET.

SIR,—In a recent issue (June 15th, p. 1261) you dealt with the report on the Carbohydrate Value of Foods, issued by the Medical Research Council. This report inquires, "In time of need is it a *national* economy to feed wholemeal bread instead of white? . . . The answer depends on how efficiently the milled off bran can be utilised—e.g., for animal nutrition. . . . It depends upon the coarseness of the bran left with the meal and the amount of it."

The proper answer to this inquiry is given in the Report of the Food (War) Committee of the Royal Society on Digestibility of Breads. In response to a memorial from the Bread and Food Reform League, the Food (War) Committee of the Royal Society carried out important investigations at the Universities of Cambridge, Glasgow, and London bearing upon the effect of raising the scale of extraction of wheat to 90 per cent. and to obtain information as to how far the economical use of the national diet would be affected by changes in the milling standard. The researches made show that bread made from meal ground so that it could *all* pass through a 10-inch mesh wire sieve could be utilised by almost everyone. The bread used was well made, was submitted to clerical and strenuous workers, to women and children—and met with general approval. The important investigations undertaken by the Food (War) Committee of the Royal Society proved, the Report states, that by increasing the extraction of wheat from 80 to 90 per cent., there would be a gain of energy available for man "equivalent to an increase of about

---

[1] Mental Handicaps in Literature. By Edwin Marion Cox, M.D. With foreword by Theo. B. Hyslop, M.D., F.R.S.E. London: Baillière, Tindall, and Cox, 1929. Pp. 93. 3s. 6d.

1,700,000 calories of energy on the wheat milled each year in this country before the war or enough to extend the cereal supply of energy for more than one month." There would also be a gain of protein "equivalent to an increase of about 90,000 tons of protein on the wheat milled each year in the country."

Calories are, however, a very inadequate gauge of food and nutrition and apt to be misleading. This report from the Royal Society does not deal with the fact that wheat contains essential vitamins and organised mineral substances extracted from wheat in the manufacture of white flour. Digestion experiments show that these phosphates can be assimilated when the meal is finely ground. White flour is an imperfect food deprived of elements necessary for the maintenance of life. Birds fed on it and water have died, whilst those fed on wholemeal and water remained strong and healthy.

The report on Digestibility of Breads, however, enabled the Food (War) Committee to advise the Government to introduce a war bread of 90 per cent. extraction. It was often very badly made, but the nation was thus saved from what the late Mr. Bonar Law stated was the greatest peril encountered during the war—namely, starvation from enemy submarines.

I am, Sir, yours faithfully,
MAY YATES,
Founder and Hon. Secretary, The Bread and Food Reform League.

37, Essex-street, London, W.C.

MEDICINE IN WARTIME.[1]

THE Fourth International Congress of Military Medicine and Pharmacy was held in Warsaw in 1927. A summary of the important conclusions reached, and an account of the hospitable entertainments arranged by the Polish hosts has been set out in a small book which reached us this summer, when the fifth Congress was held in London. The decisions of the Congress are reported at length. In 1927 evacuation of wounded by air took a prominent place in the discussions, and as regarded evacuation generally the Congress decided that only if the high command had in advance fully acquainted the medical staff with its hopes and intentions could the best work be done for the wounded after a battle. As regards epidemic influenza, the best way of limiting an epidemic was thought to be in prompt diagnosis and immediate isolation; staffs of hospitals should be masked. To lessen the serious sequelæ of head wounds it was of first importance to secure that they should heal by first intention. Damage after arsenobenzol injections was thought generally due to unwise selection of the particular drug employed; only those thoroughly understood and approved, and with an arsenic content between 19 and 20 per cent., should be used. This matter was discussed by commissioned pharmacists of continental nations, no officers of similar rank and experience being present from the United States or Great Britain. The dental services took part for the first time in the fourth Congress. This record of an important Congress is in convenient form, and provides a readily available index to the extensive official reports that will be found in the greater libraries.

WOODHALL SPA.

THE Alexandra Hospital is this year supplementing its 34 beds for spa treatment by adding rooms for Plombières douches and for electrical treatment, as well as increasing the accommodation for its nurses. The bathing establishment was kept open throughout last winter for the first time, and the number of patients resorting to its bromo-iodine water has necessitated the provision, adjacent to the Bath House, of a hostel for those more advanced cases who at first find difficulty in reaching the hydropathic and electric treatment rooms, or who require definite nursing care. The need for fuller investigation is being met by the equipment of a pathological department, able to deal with disorders of metabolism, diabetes and the like, for which in this area no means for special treatment exist.

COUVADE.[2]

THE origin is unknown of the curious old custom, known as couvade, which still survives in some parts of the world: there the father lies in after the birth of a child instead of the mother, undergoes dietetic treatment, and receives the congratulations of the family friends. Mr. Dawson sets out the details of a religious rite practised in Cyprus and Ireland, which seems to have the couvade custom as an underlying feature, and proceeds to collect evidence that this custom is known in Europe, Africa, Asia, the Islands, and America. The last part of the book deals with the geographical distribution more fully. The author states that "the recorded localities in which couvade is, or has been, practised correspond to a remarkable degree with those associated with megalithic monuments and with customs usually connected with what has conveniently been called the heliolithic culture-complex, a complex comprising many curious customs and beliefs, amongst which may be specially mentioned sun-worship, mummification, ear-piercing, tattooing, and cranial deformation." Butler appears to have been misled by a story of Marco Polo when he alluded to the couvade in Hudibras:—"For though Chineses go to bed, and lie in, in their ladies' stead"—for the Chinese do not practise couvade, though it occurs in Japan. Incidentally, the reference to Hudibras given by Mr. Dawson (iii., canto i, 70) does not correspond with the lineation in our own copy of that work, where the lines are 707 and 708. The book is well got up, and there is a valuable bibliography; the frontispiece, which curiously enough is taken from a late Chinese manuscript on loan to the Victoria and Albert Museum, shows the couvade. It would be interesting to learn whether the subject was ever made the decorative theme on oriental china such as plates or utensils.

A HEALTH PROPAGANDA.

AMONG the good work which is being done by the Health and Cleanliness Council is the distribution of literature in coöperation with health societies, local authorities and other organisations, forming health propaganda. Last year the Council sent some 5,000,000 of its various booklets and leaflets to 2300 districts in England and Wales, while their publication, "Health and Cleanliness" is used as a text-book by teachers in many schools. The latest publication of the Council is a fairy tale, "On the Arch of the Rainbow," written by Mary Tyreman, its purpose being to inculcate in the minds of children the health value of soap and water and the need for smoke prevention. The book is attractively written and illustrated, and the Health and Cleanliness Council is prepared to distribute from the office, 5, Tavistock-square, London, W.C., a number of copies without charge to teachers, Girl Guide captains, and others interested in the teaching of hygiene among children.

THE NATION AND ITS FOOD.

THE production and distribution of food of the best quality at the very lowest possible price must benefit the community as a whole. People cannot be educated to choose the best kinds of food on which to maintain themselves and their families if such food is beyond their purchasing power. The actual price paid by a consumer for his comestibles includes, of course, the costs of transportation and retailing, and in many foodstuffs these are appreciably greater than the total costs of production. Dr. Addison discusses in a pamphlet[1] recently issued various ways in which the price of food might be reduced. He refuses to believe in the present system, under which we are told that it costs as much to retail a side of beef as it does to rear and feed the animal for three years, and that the expense of transporting and selling a cabbage is two or three times as great as that of cultivating it. If the nation does not deliberately take steps to devise a more rational system of production and marketing, Dr. Addison forsees that our food-supplies will shortly be controlled by huge combines of first-rate business men operating for profit, who will be in a position to dictate the price of all our essential articles of food. He sees no reason why the nation, with its experience of food control during the Great War, should not establish a National Marketing Board which would be furnished with a monopoly of the power of import and the sole right of purchasing for import. One of its main functions would be to keep prices steady for reasonable periods, as far as possible, with the object of encouraging production. It would trade as a responsible business organisation, presenting audited balance sheets to Parliament, and would aim at operating without incurring loss or accumulating profits. The scheme sketched out represents the nationalisation of our food-supplies, and even Dr. Addison suggests that it would be necessary to introduce it gradually, while experience in working out the details is being obtained. Those opposed to any form of nationalisation will obviously disagree with all of the suggested proposals. Nevertheless the fundamental principle of securing the ability of the poorer members of the community to purchase adequate quantities of such protective foods as are at present only too often beyond their means, cannot but be regarded with sympathy.

Lectures

ON THE

PHYSIOLOGY OF GLYCOGEN

AND THE

RÔLE OF INSULIN AND EPINEPHRINE IN CARBOHYDRATE METABOLISM.

Delivered at the London Hospital

BY J. J. R. MACLEOD, M.B., LL.D. ABERD.,
D.Sc. (HON.) TORONTO, F.R.S.,
REGIUS PROFESSOR OF PHYSIOLOGY IN THE UNIVERSITY OF ABERDEEN.

LECTURE II.*—(PART I.)

THE RÔLE OF INSULIN AND OTHER HORMONES IN THE CONTROL OF CARBOHYDRATE METABOLISM: KNOWLEDGE GAINED BY STUDYING DIABETES.

SINCE insulin removes all the symptoms of diabetes it might be expected that an examination of the disturbances which cause them would reveal the nature of the action of this hormone. Let us in the first place, therefore, see to what extent this expectation has been realised. The symptoms of diabetes are so numerous that it is necessary for our purpose to decide which are fundamental, or primary, and which are merely secondary. Hyperglycæmia and glycosuria are certainly secondary and ketonæmia is also probably so, since it develops late. This leaves: (1) The low R.Q. (respiratory quotient) and its failure to become raised when carbohydrate is ingested; (2) the decrease of glycogen in the liver; and (3) excessive gluconeogenesis, as the primary symptoms. It has been customary to regard the first of these, the low and stationary R.Q., even during ingestion of carbohydrate, as evidence of a failure on the part of the organism to oxidise this foodstuff. Indeed, this is considered by many as the fundamental cause of the other symptoms, especially since, besides the low quotient, it has sometimes been possible, either on dogs rendered diabetic by complete removal of the pancreas or on these and other animals manifesting some of the symptoms of this disease as a result of repeated injections of phlorhidzin, to recover ingested glucose completely in the urine, and to observe a fixed daily ratio between the amounts of glucose and of nitrogen excreted in fasting or in meat-fed animals. Recent work, however, has failed to show that these results are always obtained, and since this greatly lessens their value as *proofs* we must examine them more fully.

IS OXIDATION OF SUGAR DEPRESSED IN DIABETES?

When glucose is given to either depancreatised or phlorhidzined dogs it *causes an immediate increase* in the amount excreted by the urine, and if we could assume that no change occurred in the endogenous metabolism it would be legitimate to compute the amount of unused glucose excreted by subtracting, *from the total glucose excretion following ingestion of* the sugar, that of a previous period of equal duration. But the nitrogen excretion usually declines decidedly as a result of the ingestion, so that, in order to allow for the lesser amount of glucose which this indicates *must be coming from protein metabolism, the sub*traction has to be made from a value which is obtained by multiplying the nitrogen excretion of the ingestion period by the D/N ratio of the previous period. Following the ingestion of moderate quantities *of glucose both in depancreatised and in phlorhidzin*-poisoned dogs a tolerable balance between the amounts ingested and excreted in excess is sometimes obtained under these conditions, but this result cannot be accepted as proof of the inability of the tissues to utilise the glucose, for if this were the case then no change should occur in protein metabolism. The method of calculation allows for this change, and nevertheless the results are supposed to prove that the glucose is not utilised. But, quite apart from this obvious fallacy, the actual results often fail to show close correspondence, either when they are thus calculated or when they are taken as a simple balance between intake of sugar and the excess which is excreted.

The Significance of the R.Q. in Diabetes.

This brings us to a consideration of the significance of the supposed fixity of the R.Q. as evidence of the inability of the organism to oxidise carbohydrate. In phlorhidzined dogs it is now known, through work *emanating from Lusk's laboratory, that the R.Q.* may rise considerably when sugar is fed, especially in divided quantities at intervals of an hour or two apart and, when allowance is made for the larger amount of carbohydrate which this shows is being *metabolised, the excess excreted may actually* exceed the amount taken. It must be remembered, however, that such animals are not truly diabetic, because they still can secrete insulin from the intact pancreas, and the variable effects which have been observed following the ingestion of sugar may depend on variations in the internal secretion of insulin. It is important, therefore, to consider the effects of ingestion of sugar in depancreatised dogs which are truly diabetic, inasmuch as there can be no internal secretion of insulin. When moderate amounts (20–40 g.) are given to such animals at one time there is seldom any effect on the quotient and most of the sugar can be recovered in the urine, but some preliminary experiments by de Peucier have shown that administration of sugar in divided quantities may cause the quotient to become raised *and a considerable proportion of the amount* ingested may fail of recovery in the urine. Hédon [24] has also reported numerous observations in which the R.Q. in depancreatised dogs rose considerably above the "diabetic" level of 0·707 at later stages after the withdrawal of insulin.

Neither in phlorhidzin-poisoned animals nor in depancreatised ones, therefore, does the behaviour of the R.Q., or the increase in sugar excretion following the ingestion of sugar, justify the claim that the organism has entirely lost the power to oxidise carbohydrate. There is, moreover, evidence to show that the diabetic organism can utilise the blood-sugar at a rate which is not demonstrably less than that in normal animals. Let me, very briefly, cite this evidence. When the abdominal viscera are removed in an anæsthetised dog or a decapitate cat the blood-sugar falls rapidly, and the speed at which it does so is apparently the same in a diabetic (depancreatised) animal as in a normal one (Macleod and Pearce,[25] Burn and Dale, &c.). Objection may be taken to these experiments on the ground that the fall in blood-sugar level in both normal and diabetic animals is somewhat irregular. This irregularity did not occur in the experiments of Markowitz, in which the liver alone was removed, in dogs, after making provision so that the blood could get from the posterior parts of the body to the heart independently of the inferior vena cava and portal vein. During the survival of the animal under these conditions the blood-sugar steadily falls, and it does at about the same rate in diabetic (depancreatised) as in normal animals, when allowance is made for the initially higher level of blood-sugar in the former

But, although *diabetes causes no significant change* in the rate at which sugar migrates from the blood into the muscles, this does not necessarily mean that the sugar has been equally well oxidised in both cases. We must be careful to distinguish between utilisation and oxidation. *Indeed there is evidence to show that* the diabetic tissues have lost something of their oxidative power. Thus, by measurement of the respiratory exchange from hour to hour, Markowitz found that the R.Q. behaved in the same manner immediately *after hepatectomy in diabetic* as compared with normal animals, but that it showed a difference later on. In both normal and diabetic animals the quotient to start with stood at between 0·85 and 0·90, but whereas intravenous injection of glucose, to compensate for the rapidly developing hypoglycæmia, caused the quotient to rise to unity in the normal animal, it failed to affect it in the diabetic (Table VII.). There was also a difference in the behaviour of the calorie expenditure; in the normal animal this became markedly raised by giving sugar, but it was unaffected in the diabetic. We can suggest no cause for these differences unless it be related to the lingering presence of insulin in the tissues of the normal animals. In other words, the blood-sugar and muscle glycogen originally present in both conditions may be directly utilised by the muscles, but glucose from without be utilisable only in the presence of insulin still remaining in the normal tissues.

---

* Lecture I. appeared last week and Part II. of Lecture II. will appear in a coming issue.

TABLE VII.

Time and condition.	Calories per kg. per hr.	R.Q.	Remarks.
Non-diabetic.			
9.40 A.M. .. .. Hepatectomy completed.	—	—	Wt. 7·8 kg.
10.15–10.30 .. .. Recovered from anæsthetic; put in cabinet.	—	—	Blood-sugar 0·074 %.
11–12	2·00	0·869	Animal quiet.
12.10 P.M. .. .. Removed.	—	—	Hypoglycæmic symp. Blood sugar, 0·052 %. Glucose injected; prompt recovery. Animal replaced in cabinet.
12.50–1.50	2·14	0·990	Animal quiet.
1.50–2.50	2·25	0·987	
2.50–3.50	2·43	0·936	
3.50–4.50	2·32	0·902	
6	—	—	Blood-sugar 0·100 %. Animal in good condition.
Diabetic.			
9–9.40 .. .. .. Hepatectomy completed and put in cabinet.	—	—	Wt. 12 kg. Depancreatised 2 days prev.
10–11	2·65	0·857	Very quiet.
11–12	2·63	0·886	
12–1	2·28	0·887	
1–2	2·05	0·855	Convulsions at end of period.
2.5 .. .. .. Removed.	—	—	Blood-sugar 0·054 %. Glucose injected; recovery.
2.35–3.35	1·70	0·831	Quiet.
3.35–4.35	1·63	0·851	Unconscious part of time.
5.30	—	—	Blood-sugar 0·042 %.

Objection may be taken to all of these experiments on the ground that the gases of the blood were not measured at the same time as the respiratory exchange. This objection would seem to be justified in light of the experiments of Verzar, Murlin, and Kramer, and, more recently, of Kilborn,[30] who have shown that the CO_2 content and the CO_2-combining power both decline markedly following evisceration, mainly because of relative over-ventilation of the blood in the lungs and a consequent blowing-off of CO_2. Indeed, the last-mentioned worker has shown that if precautions be taken to prevent the fall in CO_2 content—by breathing air with about 2 per cent. CO_2—the R.Q. does not become raised by evisceration. But it is unlikely that these results on eviscerated animals, which are either under anæsthesia or are decapitated, apply in the case of an animal in which the liver alone is removed, and the respiratory centre is intact. Moreover, there is a significant difference in the behaviour of the quotient in the two conditions, for it steadily rises from hour to hour after evisceration, whereas it falls after hepatectomy. There is therefore no reason to suppose that the rise in R.Q. following hepatectomy is due to any other cause than a change in the type of metabolism. In intact animals the quotient is the algebraic sum of a very low quotient contributed by the liver, because gluconeogenesis occurs mainly here, and a high one contributed by the muscles, where carbohydrate oxidation is the predominant process. That the quotient does not actually rise to unity after hepatectomy merely means that the muscles themselves possess some powers of gluconeogenesis. These become suppressed entirely when there is a plethora of carbohydrate in the presence of insulin.

Muscular Exercise in Diabetes.

To return to our main question—namely, is oxidation of carbohydrate seriously depressed in diabetes, there still remain two further types of experimental evidence to be considered. The first relates to the behaviour of the respiratory exchange following increased muscular activity, in normal as compared with diabetic (depancreatised) animals. It was found by Chaikoff and Macleod,[21] who induced greater muscular activity by exposing the animals to cold, that there is no difference between normal and diabetic animals. The consumption of oxygen in both cases usually became more than doubled during the first hour following exposure to cold, and the R.Q. rose as decidedly in the diabetic as in the normal animals. The results of these experiments are shown in Table VIII.

TABLE VIII.

Dog No. and weight in kg.	Respiratory exchange.					Excess R.Q. of first ¼ hr.
	Resting*	Shivering.

* Average of four hour observations. † 1 hour observation.
Note.—The weight of the dog and the respiratory quotient are shown in parentheses.

Heart-lung Preparation.

The second type of evidence is obtained from observations on the respiratory exchange in the heart-lung preparation. Notwithstanding the considerable experimental difficulties which are encountered in experiments of this type it has been established that the R.Q. is about 0·85 for the heart of normal (fed) dogs, but is much lower (about 0·7) for diabetic ones, and that whereas the quotient becomes raised somewhat (to 0·9) by adding glucose to the perfusion fluid in the case of normal hearts this does not occur when diabetic hearts are used. But these results do not furnish conclusive evidence that the diabetic heart had lost the power to oxidise carbohydrate because, as Starling and Evans [32] point out, profound modifications in tissue metabolism may serve to mask a moderate carbohydrate combustion. Moreover, it must be borne in mind that the heart is a mechanism of a somewhat different type from the skeletal muscles, as is evidenced by its power of prolonged beating when perfused with oxygenated artificial plasma, the formation of glycogen in it during starvation and in diabetes, and the peculiar behaviour of lactic acid.

We would sum up all this evidence as showing that the diabetic musculature still retains the power to oxidise carbohydrate, and if some of it may indicate an enfeeblement this is probably secondary to some other metabolic disturbance which interferes either with the preparation of the carbohydrate for combustion or with its derivation from other foodstuffs. We cannot therefore explain the action of insulin by stating that it directly stimulates the oxidation of carbohydrate.

DECREASED LIVER GLYCOGEN IN DIABETES.

What, then, is the *fundamental metabolic fault* in diabetes? What, in other words, is it that insulin controls so as to prevent this disease? Two other disturbances remain to be discussed—great reduction of the amount of glycogen in the liver and excessive gluconeogenesis. With regard to the former, although it is a striking fact that only traces of glycogen can be found in the liver of diabetic dogs, even after feeding with sugar, yet it is, I think, most important to remember that glycogen is seldom if ever entirely absent. We have always been able to detect its presence in the liver even after there has been total diabetes for several days, but it is possible that all traces might disappear if depancreatised animals were kept until they were moribund, and it is said that there is complete absence in phlorhidzin poisoning. The fact that some glycogen usually remains, however, indicates that the glycogenic function is not abolished. The glycogen found after death merely represents what is left over as the result of the action during life of two opposing processes, one of which—glycogenolysis—proceeds in the normal animal somewhat slower than the other—glycogenesis, whereas in diabetes the former process almost keeps pace with the latter, so that only a trace of glycogen is left over.

INCREASED GLUCONEOGENESIS IN DIABETES.

The evidence for the occurrence of excessive gluconeogenesis in diabetes is that large quantities of sugar continue to be excreted by a fasting animal long after all the carbohydrate which was stored in the body before the diabetes set in has been exhausted. Thus between the third and fifth days after the withdrawal of insulin and food from a well-nourished, depancreatised dog weighing 8·6 kg., as much as 52·7 g. of glucose were excreted. At this time there is not more than 1·2 g. of glycogen in the liver and possibly a total of 3·5 g. in the muscles, an amount which, in toto, is insufficient to furnish the energy required for living for more than an hour or so, let alone the sugar which is excreted. If, as is the present-day teaching, carbohydrate is the fuel which alone can be used by muscle for the production of energy, we must conclude that in the diabetic organism the process of gluconeogenesis, by which protein and fat are converted into glucose, is proceeding so actively that it provides an excess of carbohydrate which appears in the urine as glucose.

Gluconeogenesis is no doubt mainly a function of the liver, but it may also occur in the muscles themselves, as is evidenced by the fact that the R.Q. of diabetic animals after hepatectomy is well below unity (0·9). I have pointed this out in previous lectures,[23] and since then Cori and Cori,[24] basing their conclusions partly on work of their own and partly on that of Krogh and Lindhard, have drawn a distinction between the hepatic and the muscular processes of gluconeogenesis. They believe that glucose is a necessary product of the process in the liver, but is not so in that occurring in the muscles, and they assume that it is only the glucose produced in the liver which is excreted in diabetes. If we make the further assumption that the muscles cannot use this sugar, such a view is compatible with the known fact that the amount of glucose excreted daily by a fasting diabetic animal is tolerably constant, and it would explain why the blood-sugar apparently falls after hepatectomy as quickly in a depancreatised as in a normal animal. At the same time it implies that the muscles in diabetes have lost their power to oxidise the sugar brought to them by the blood, although they still retain that of forming glycogen. There is much to be said in favour of these views, and they are opposed to that which supposes that the diabetic animal derives most of its energy by a direct oxidation of fatty acid and of protein. This is the orthodox view, and it is based on the supposed constancy of the D/N ratio and the R.Q. in animals under the influence of phlorhidzin. As we have pointed out elsewhere, neither of these values is actually fixed in depancreatised animals.

But for our present purpose the important conclusion arrived at is that gluconeogenesis is proceeding excessively in the liver, where, also, deposition of glycogen has become reduced to a very low level. To what extent these two processes are linked together cannot be stated. It would be simplest to imagine that glycogen is formed in the liver in an inverse ratio to gluconeogenesis from protein and fat, the maximal deposition occurring when, in a normal animal, carbohydrate is being absorbed from the intestine and the least, in a diabetic one in which, owing to the absence of insulin, gluconeogenesis is at its maximum. *This view is not incompatible with the known fact* that glycogen accumulates somewhat in the liver during starvation in normal animals, for here it may be derived from lactic acid coming from the muscles, where it is derived from glycogen produced there by gluconeogenesis. It is, however, difficult to reconcile this view with the continued large deposition of glycogen and the excessive gluconeogenesis caused by epinephrine. We will discuss this question further at a later stage. Meanwhile the important thing to remember is that administration of insulin to the diabetic animal immediately causes glycogen to appear in the liver, not only when carbohydrate is also fed to the animal, but also without it (Cori). The question is whether the excessive gluconeogenesis is also checked. It is usually concluded that it is so since the nitrogen excretion becomes lessened, but otherwise there is no direct evidence to support this view. The behaviour of the R.Q. is often cited as further proof. This rises shortly after insulin is given. In a fasting, diabetic animal this cannot be dependent simply upon more *carbohydrate being burned since* there is, as we have seen, very little available carbohydrate and, as a matter of fact, more becomes deposited as a result of insulin. Hence the change in the quotient must depend on relatively less oxygen being required for gluconeogenesis, and since the actual oxygen consumption does not fall it is usually assumed that, pari passu with the lesser gluconeogenesis, there is an increased combustion of carbohydrate. The interpretation of changes in R.Q. is, however, very difficult, so many *factors* being involved.

Although the rise in R.Q. following insulin is compatible with the view that gluconeogenesis has become lessened it is no proof that this is actually the case. It is indeed impossible to get direct evidence that insulin inhibits gluconeogenesis. The most recent experiments are those of Burn and Marks,[25] who have used the artificially perfused, excised liver. They found that the total carbohydrate of liver and perfusion fluid became markedly increased as the perfusion proceeded, but was not affected by adding insulin to the *perfusion fluid*.

It is impossible in the light of present knowledge to decide what really is the primary metabolic fault in diabetes, and therefore to say how insulin acts in preventing this disease. It certainly cannot do so merely because it inhibits excessive gluconeogenesis in the liver, as was the view put forward several years ago by Laufberger.[26] If such were the case then insulin should fail to lower the blood-sugar in hepatectomised and eviscerated animals, but it quickly lowers it, as was first shown by Mann and Magath. If gluconeogenesis also occurs in muscle Laufberger's view might hold.

Striking as may be the effects of insulin on the metabolism of depancreatised animals their investigation has taught us really very little regarding the fundamental nature of its action, and the chief reason for this failure is the necessarily limited number of experiments that can be done, the dog being the only laboratory animal suitable for pancreatectomy. If more could be learned concerning the quantitative behaviour of glycogen in the liver and muscles at various stages following administration of insulin to fasting, and to sugar-fed, diabetic animals, and the changes in glycogen formation compared with those in respiratory metabolism and in the relative concentrations of sugar and lactic acid in the blood entering and leaving the liver and muscles, great strides forward could, I am sure, be taken. On account of these difficulties the problem of how insulin acts has mainly been attacked by observations on the effects produced by injecting it into normal animals, especially rabbits, rats, and mice.

EFFECT OF INSULIN ON NORMAL ANIMALS.

In such experiments, however, it has at the outset to be recognised that we are dealing with a condition that is essentially different from that which is set up by giving insulin to diabetic animals. The insulin we inject in the latter case restores to normal a completely disorganised metabolism and any excess is probably quickly destroyed or excreted, whereas in normal animals it distorts the whole of metabolism by overstimulating certain phases of it. The excess causes some parts of the metabolic machinery to go too quickly or too slowly for other parts upon which it has no influence. Such disorganisation may lead to the accumulation of intermediary products of metabolism having a detrimental influence on the working of the machine as a whole. It may be because of a mechanism of this type that those toxic products accumulate which are responsible for the symptoms of hypoglycæmia and here I may refer to the work of Hynd, who suggests that accumulation of a substance called "glucosone" is responsible.

Increased Glycogen Formation and Carbohydrate Combustion.

In the light of the results obtained by insulin on depancreatised dogs, it was natural to expect that increased glycogen formation and increased oxidation of carbohydrate would together account for the disappearance of blood-sugar following injection of this hormone into normal animals. But it was impossible to demonstrate that this occurred; on the contrary, it was found that the glycogen of the muscles and of the liver actually diminished after insulin, and, although the respiratory quotient often changed so as to indicate a relatively increased combustion of carbohydrate, this did not always occur (in rabbits and dogs) until after the blood-sugar had completed its initial fall. In small animals, such as rats and mice, moreover, although the quotient might rise there was an absolute decline in carbohydrate metabolism and when glucose was given along with the insulin, it seemed impossible to account for the disappearing sugar by increased glycogen formation and increased carbohydrate utilisation. These results suggested the possibility that some hitherto unidentified intermediary product of carbohydrate metabolism was accumulating, and attempts were made, by chemical examination of the muscles and liver, to reveal its presence. The plan adopted in these experiments was to compare the amounts of glycogen, lactic acid, free sugar and lactacidogen in the liver and muscles of normal rabbits and of rabbits previously injected with insulin and sugar. It was found that less rather than more of each of these substances was formed in the injected animals. This result in itself would not, however, be inconsonant with the idea that some unknown substance had accumulated—for all of the bodies mentioned might have been used to form it—but if this were carbohydrate in nature, its presence should be revealed by an increase in the total sugar set free by hydrolysis, with acid, of the tissues (liver and muscles) of the insulin-treated animals. But the results of such experiments proved to be entirely unsatisfactory, partly because of their irregularity and partly also because of lack of knowledge as to what really happens when extracts of tissues containing proteins, as well as various extractives, are subjected to acid hydrolysis. When hydrolysis is performed with deproteinised tissue extracts the reducing power, originally small, is only slightly increased, and there is no difference between normal tissues and those removed from insulin-treated animals.

This failure to demonstrate the formation of an intermediary substance revived consideration of the possibility that, after all, insulin acts on normal animals, either in the same way as on diabetic ones—namely, by causing more glycogen to be formed, by increased carbohydrate combustion, and by suppressing the new formation of carbohydrates (Best, Dale, Hoet and Marks)—or, more simply, by merely stimulating glycogen formation and carbohydrate combustion (Lesser, Bissinger et al, and Cori and Cori). Each of these three groups of workers have performed experiments in which an endeavour has been made to compare, on the one hand, the amount of extra sugar disappearing as a result of insulin action, and, on the other, the increase in carbohydrate combustion—as calculated from the respiratory exchange—and the increase in glycogen deposition—as found either by analysis of the entire animal or of a supposedly representative fraction of it. Although I consider these experiments a very great advance over those performed by myself and my various co-workers, especially since they open a new avenue of approach to the investigation of the problems of carbohydrate metabolism, there are, nevertheless, several possible sources of inaccuracy in them, and I hope it will not be taken amiss if I take this opportunity to indicate some of these.

Experiments on Mice.

The first researches were those commenced in 1923 by the late E. J. Lesser, of Mannheim, and his collaborators, Issekutz, Bissinger, MacGrath, &c.[38] Mice were used, and in the first observations it was found that when insulin was injected along with sugar it caused more to disappear from the entire animal than when sugar alone was injected. In the absence of sugar injections, it was also found that insulin caused the total reducing substance (reckoned as glucose) plus the glycogen to become less in the animal. Thus MacGrath found an average of 54 mg. glucose and 63 mg. glycogen per 100 g. in untreated mice, and 26 mg. glucose and 57 mg. glycogen in others injected 30 minutes previously with insulin. The chief reduction was therefore in the tissue glucose and in all only 34 mg. of carbohydrate had to be accounted for—an amount which was inadequate to raise the R.Q. beyond the limits of experimental error. This made it impossible, by respiratory analysis, to determine whether all of the lost carbohydrate had been oxidised, so that the experiments were repeated with the difference that glucose was injected along with the insulin. The results showed a very close correspondence between the glucose which actually disappeared from the body and the amount which could be accounted for by respiratory analysis. It was noted also that glycogen synthesis was only moderately increased by the insulin injections. The authors point out that estimation of the extractable reducing substance as glucose may be fallacious and that substances having a lower reducing power, such as hexose phosphate esters, might have been formed in their experiments. Lesser, nevertheless, concluded from his researches that insulin acts by accelerating the oxidation of glucose and its synthesis to glycogen, and taking into consideration the work of others, as well as his own, he further concluded that it is in the voluntary muscles that this acceleration occurs.

Experiments on Eviscerated Spinal Preparation.

We will next consider the evidence of Best, Dale, Hoet, and Marks.[11] This was obtained from experiments on an eviscerated spinal preparation (cat), in which *the total loss of glucose* was calculated from: (1) the actual amount of glucose infused; (2) the *decrease in blood-sugar*; (3) *the decrease in the* "free sugar" of the muscles; and (4) the sugar added to the blood stream from the liver—as found from the decrease in the total carbohydrate (glycogen and "free sugar") of this organ; and the *carbohydrate utilised* from (1) the increase in the glycogen of the muscles, and (2) the increase in oxygen consumption. An almost exact balance was obtained between sugar disappearing, on the one hand, and that accountable for by increased oxygen consumption and glycogen formation, on the other hand, and the authors drew the conclusion that "the glucose which disappears from an eviscerated spinal preparation under the action of insulin is equal to the sum of the glycogen deposited in the muscles and the glucose-equivalent of the oxygen absorbed." I do not think that this conclusion should be accepted as final because of the following possible sources of error in the experiments:—

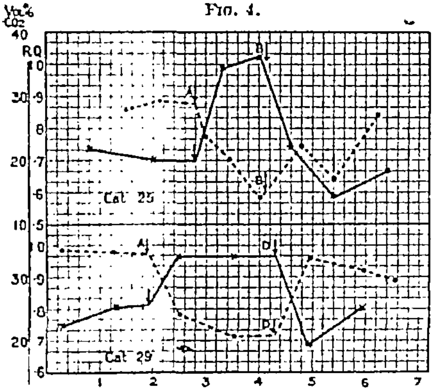
(1) *The decrease in the free sugar of the muscles* was determined by measurement of the reducing power (Hagedorn-Jensen method) of a watery solution of the residue obtained by evaporation of an alcoholic extract of muscle, after treating it with colloidal iron. The values found for different muscles of one leg of a spinal cat averaged 0·22 per cent. and no significant change occurred after leaving the preparation at body temperature for five and a half hours. The authors express doubt as to whether this is really "free sugar," but they believe, since the experiments are comparative ones and glucose "the only muscle constituent likely to vary significantly under the conditions of the experiment," that it is justifiable to consider a change in reducing power as due to glucose. After insulin they found that this free sugar declines in percentage and when allowance is made for the mass of all the muscles "a much larger contribution (is made) to the total of glucose lost than does the larger fall in the blood-sugar percentage" (bracketed words mine). Thus, in a cat weighing 3·725 kg. 0·42 g. glucose was calculated as being lost from the blood (the percentage falling from 0·27 to 0·088) and 1·44 g. from the muscles (the average percentage in four muscles falling from 0·202 to 0·182). Obviously, therefore, this is an important item on the credit side of the account, and it amounts, in two other experiments that are recorded, to 0·060 g. and 0·200 g. (the glucose infused being 3·250 g. and 4·80 g. respectively) and to 0·120 g. in another, in which the glucose infused, 1·080 g., was insufficient to prevent hypoglycæmia from developing. These figures show that the correction for free sugar varied greatly in the different observations and they raise the question whether, even with the reservations made by the authors, the figures can be taken at their face value. While there is no pretence that the reducing power gives a correct estimate of glucose present in the extracts, yet it is assumed, since the blood-sugar was being artificially maintained at a high level (which, however, was not the case in the third experiment referred to above), that the change in reducing power would represent a change in sugar to the same degree as a similar change is taken to represent one in blood-sugar percentage. Then again, Simpson and Macleod and Cori and Cori, using somewhat similar methods for estimating the free sugar of muscle in the rabbit and rat, have not found that insulin does lower the percentage of free sugar. With these points in view the risk involved in multiplying the actual changes found by a large factor are perhaps even more considerable than the authors imagine.

(2) *The sugar added to the blood stream from the liver* is allowed for by determination of the total of free sugar and glycogen in samples of liver removed at different stages of the experiment. It was found in a control experiment without insulin that the total loss of carbohydrate from the liver during a period of 50 minutes plus the sugar injected almost corresponded to the glucose equivalent of the oxygen meanwhile used, without there being any change in muscle glycogen. This result seems to justify the correction, but it appears to me doubtful whether the percentage of carbohydrate in a small portion will invariably represent that present in the liver as a whole. Since there was practically no circulation in the organ, it is not likely that the sugar in various portions of it would drain to an equal extent into the cava blood.

Coming now to the other side of the balance sheet the glycogen deposited in the entire musculature is computed by multiplying the average percentage found in four muscles of the hind limb by the estimated weight of all the muscles. The reliability of this method is fully discussed in a paper by Best, Hoet, and Marks[11] and certain of its possible sources of inaccuracy are pointed out. But there are several curious properties of the eviscerated preparation which seem to me to indicate that it does not behave like the muscles of an intact animal. In the first place, as I have pointed out elsewhere, it is difficult to reconcile the constancy in glycogen in the muscles over several hours in preparations not injected with insulin with the current hypothesis that the immediate fuel used for the production of muscular energy is glycogen. The energy production in these preparations, which was at the rate of about 2 calories per kg. an hour, was apparently not dependent on glycogen, since this was the same at the beginning as at the end of the experiment, or if it was dependent on glycogen then we have to imagine that in each of the muscles just as much glycogen was being built up out of blood-sugar as was disappearing during the course of the experiment. The other alternative is that the fuel used was blood-sugar itself. The amount of sugar which analysis showed to be disappearing from the blood itself was far from adequate to account for the energy produced, but, when the sugar that was considered to be leaking into the systemic circulation from the liver was added to this, a sufficient amount was found to be provided in one of the experiments of Best, Dale, Hoet, and Marks. In either case there is something mysterious about the energy metabolism of the spinal preparation.

Even were these sources of error overcome there remains a more serious one, and this depends on the assumption that each 750 c.cm. of oxygen retained by the preparation corresponds to the oxidation of

FIG. 4.



The interrupted lines represent CO_2 in blood (volumes per cent.), and the continuous lines represent the respiratory quotient. A = eviscerated. B = lessened ventilation. D = breathing expired air. Time in hours.

1 g. of glucose. This would be the glucose equivalent of oxygen if the respiratory quotient stood at 1·0, but it is not permissible, in the light of Kilborn's experiments, to assume that this was so. Kilborn [30] in confirmation of earlier work by Vérzar and others, found that the rise in the R.Q. which follows evisceration is dependent partly on the appearance of lactic acid and partly on the relative over-ventilation of the preparation. This causes a blowing-off of CO_2 from the blood and tissues, as evidenced by a marked fall in the CO_2 of the blood, thus making it unsafe to assume that because the quotient was unity carbohydrate combustion was alone occurring in the eviscerated preparations. As a matter of fact Kilborn found that he could cause the R.Q. to return to about its original low level either by reducing the respiratory volume or by adding CO_2 to the inspired air as shown in Fig. 4. Of course, there is the possibility since there was a very high percentage of blood-sugar in the preparations used by Burn and Dale and Best et al—which was not the case in those used by Kilborn—that the metabolism may have been one exclusively of carbohydrate. In this connexion it is only fair to point out that Markowitz found in a dog from which the liver had been removed that whereas the R.Q. stood at about 0·9 to start with, it rose practically to unity when glucose was injected. There is no doubt that insulin sooner or later increases the rate of oxygen consumption, not only in decapitate, eviscerated preparations, but also in normal animals, and since the R.Q. rises somewhat in the latter it is doubtless correct to conclude that relatively more carbohydrate is being oxidised, but it is impossible to calculate the extent to which this is occurring without knowing in how far the R.Q. is being affected by a mere over-ventilation of the blood and tissues.

THE DEVELOPMENT OF PULMONARY TUBERCULOSIS,

WITH SPECIAL REFERENCE TO "EARLY INFILTRATION."

BY H. V. MORLOCK, *M.C.*, M.D., M.R.C.P. LOND.,
ASSISTANT PHYSICIAN TO THE CITY OF LONDON HOSPITAL FOR DISEASES OF THE HEART AND LUNGS, TO THE HAMPSTEAD GENERAL HOSPITAL, AND TO THE MILLER GENERAL HOSPITAL.

IN no disease is it more important to establish the diagnosis early than in pulmonary tuberculosis; to this end much literature has been produced by many authors. The disease has usually been described as being of a slow insidious onset, the chief symptoms of which are cough (often most marked in the mornings), hæmoptysis, indefinite malaise, night-sweats, an intermittent low-grade pyrexia, and a progressive loss of weight. In the early stages the disease-process has been supposed to be confined to the apical region of the affected lung, the lesion at first being very small in size and in the course of time gradually spreading to involve more and more of the lung. The literature on the subject leads to the conclusion that physical signs in the early stages are extremely variable and difficult to establish, and that they are to be found in the apical region of the affected lung. Various authors lay particular stress on some percussion or auscultatory finding which, in their opinion, is almost diagnostic. The radiological findings reported as early manifestations are almost as variable and elusive as the physical signs. The sputum in the earliest cases (closed cases) is said to be negative when examined for tubercle bacillus.

"*Early Infiltration.*"

During recent years, on the Continent, particularly in France and Germany, a great deal of evidence has been adduced to suggest that the old teaching that the development of pulmonary tuberculosis is a slow, insidious process is erroneous and that, as a matter of fact, the disease has a comparatively acute onset. Assmann,[1] Redecker,[2] Lydtin,[3] Fassbender,[4] Braeuning,[5] Kayer-Petersen,[6] Ulrici,[7] Gran,[8] Rist and Amenille,[9] Frischbier and Bechmann [10] have reported series of cases in which the disease has been characterised by the following phenomena.

1. The onset is definite and often acute.
2. The lesion is usually situated in the infraclavicular region, but may be in the mid-zone or basal area.
3. The skiagrams show a very definite, characteristic picture.

To these cases Redecker gave the name "early infiltration." (*Frühinfiltrat.*)

The following series of cases from the City of London Hospital for Diseases of the Heart and Lungs are illustrations of "early infiltration."

CASE 1.—A man, aged 28, had been quite well until two weeks before *admission, when he noticed a cough,* and a few days before admission he had had a hæmoptysis of half a drachm. He was well nourished with a good colour. His temperature was 99·4°F. The only physical sign was an occasional crepitation after coughing in the left second space. The family history was negative. The sputum was T.B. positive.

CASE 2.—A youth, aged 18, had pain in the left axilla one month before admission, and cough started. After a few days the axillary pain disappeared, and cough continued. He was rather pale, but his general condition was good. There was slight impairment of note, and post-tussic crepitation in the left axilla, the temperature during the first two weeks in hospital not rising above 99·8°. The sputum was T.B. positive. The skiagram showed in the left infraclavicular region an area of infiltration which had reached the size of a large orange.

CASE 3.—A man, aged 26, developed cough one month before admission. One day before admission he had a hæmoptysis of two ounces. He was pale, but his general condition was good. There was slight impairment of percussion note over the left second and third spaces and crepitation beneath the right clavicle. There was no alteration in the breath sounds. Pyrexia was remittent up to 101°. The sputum was T.B. positive. The patient had been in close contact with an open case. Skiagrams show a definite infiltration in the right axillary region.

CASE 4.—A girl of 19, three weeks before admission had "influenza"—i.e., cough, feverishness, and malaise. These symptoms continued until admission. She had been examined nine months before as a tuberculous contact, and no physical signs had been found. Two brothers were suffering from pulmonary tuberculosis. She was well nourished with a good colour. There was an impaired percussion note in the left axilla and left interscapular region. Crepitations were heard in these regions. She showed intermittent pyrexia up to 100° during the first *two* weeks in hospital. The sputum was T.B. positive. The skiagram shows an area of infiltration in the left axillary region.

CASE 5.—A man, aged 28, had had "influenza" nine weeks before admission. Cough continued up to the time of admission. The general condition was good. There was an impaired percussion note over the right apical region and crepitation in this region in front and behind. The sputum was T.B. positive, and there was intermittent pyrexia up to 100°. There was no family history. Skiagrams show a large area of infiltration extending from the clavicle to the third intercostal space.

CASE 6.—A girl, aged 14½ years, had an acute cold in the head three months before admission. Cough and malaise developed later, and she lost a little weight. She was a pale, ill-looking girl, but well nourished. There was an impaired percussion note and crepitations in the right infraclavicular region, and a temperature ranging up to 99·8°. The sputum was T.B. positive. Skiagrams show an area of infiltration, which is proceeding to cavitation, in the right infraclavicular region.

CASE 7.—A man, aged 23, 28 days before admission had "influenza." He was in bed for a few days and returned to business after 14 days. He was examined by the medical officer of his firm, who sent him to hospital for investigation. His general condition was excellent, but the percussion note was impaired, crepitations were heard below the right clavicle, and the sputum was T.B. positive. There was no history of contact. Skiagrams show a large area of infiltration in the right infraclavicular region.

CASE 8.—A girl of 19, two months before admission had a "feverish cold." She showed crepitation over the right upper lobe in front and her sputum was T.B. positive.

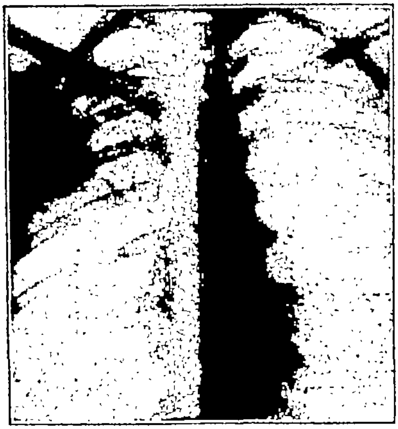
There was no history of contact. Fig. 1 shows a large area of infiltration.

The salient points in these cases are:—

1. The onset is definite, often with an acute febrile illness which may be misdiagnosed as "influenza." (Lydtin, Fassbender, and Braeuning stress the possibility of the confusion which may arise between influenza and these cases.)

2. The physical signs are present below the clavicle, usually in the second or third space, or in the upper part of the axilla, the only constant physical sign being crepitations.

FIG. 1.



Radiographic appearances in Case 8.

3. The definite radiological appearance is of an area of infiltration, which varies in size from 2 to 10 cm. or more in diameter, the area of infiltration being situated in the infraclavicular or axillary region.

4. The general condition of most of the patients is extremely good.

It might be suggested that the lesion here described is the acute broncho-pneumonic phthisis which has long been known as a clinical picture, but that is not so. In the first place, the patient with acute broncho-pneumonic phthisis is extremely ill, while the patient with "early infiltration" is not. The skiagram of "early infiltration" in the stage described is very different from that of acute broncho-pneumonic phthisis, but if the early infiltration has advanced to evolve the greater portion of the lobe, then the skiagrams may be similar. Lastly, acute broncho-pneumonic phthisis is usually fatal, while early infiltration is seldom fatal and often, when treated, improves and heals (Assmann, Redecker, Lydtin, Ulrici).

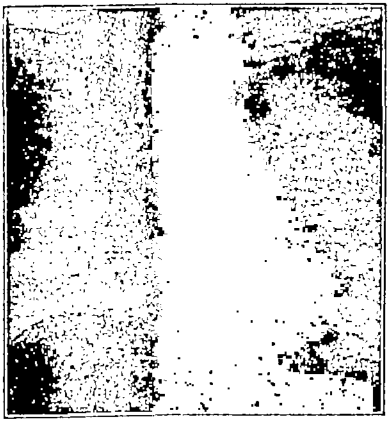
On the other hand, it might be suggested that "early infiltrations" are a particular type of pulmonary tuberculosis and have no bearing on the development of phthisis. Cases of early infiltration have been observed over a period of time and many have been seen to progress to a picture which is indistinguishable from phthisis (Redecker, Frischbier and Bechmann, Morlock[11]). It is not my intention to describe the various courses which early infiltration is known to take (a full account is given by Lydtin, Redecker, and Morlock), but to show the importance of recognising this lesion as the beginning of pulmonary tuberculosis.

The question may be asked: if "early infiltration" is really the beginning of pulmonary tuberculosis, why is it not seen more often? In the first place, like every other clinical picture in medicine, until the condition is known it is not looked for; but since the condition was first described by Assmann many series have been reported. In reviewing the skiagrams of some four hundred cases which have been treated at the City of London Hospital in the past two years, I was able to find just over fifty cases which had undoubtedly started as an early infiltration. Secondly, it must be remembered that early infiltration is a transitory lesion. In a few weeks it may spread to involve the apical region as well or it may heal in a few months to leave only a scar. If it has spread to involve the apical region before the case has come under observation, it is impossible to say if the lesion started in the apical region and spread down, or if it started as an infraclavicular "early infiltration" and progressed to the apical region.

CASE 9.—A woman, aged 25 years, three months before admission, after the birth of a child, had noticed a cough and felt ill. Cough and malaise continued up to the time of admission. Her general condition was fair. There was an impaired percussion note over the right apex in front and behind the infraclavicular region, crepitations in these areas, with slight intermittent pyrexia. There was no family history. Fig. 2 shows a lesion involving the right apical and infraclavicular regions.

When a case has reached this stage, is there any evidence to suggest which of the two processes have been at work: (*a*) early infiltration with its rapid spread or (*b*) the slowly progressive lesion, spreading from the apical region? If the latter process is the cause it would be reasonable to expect that the patient would give a history of cough and malaise extending over a considerable time. Yet in the majority of cases of this extent the patient only gives a short history (8–12 weeks). The clinician, because he believes pulmonary tuberculosis to be a slowly progressive disease, discredits the patient's history and ante-dates the commencement of the infection, although it is well recognised that as large an area of lung can be involved in a broncho-pneumonic spread in as short a period—e.g., the broncho-pneumonic spread in the "sound lung" in case treated with artificial pneumothorax (Landreth and Morlock[12]). Therefore, it seems reasonable to suggest that, in those cases which give a short history, the initial lesion may have been this rapidly-spreading "early infiltration" which has spread to involve the apical region. Over a period of seven years

FIG. 2.



Radiographic appearances in Case 9.

Braeuning, Lydtin, Redecker and Walter, and Kayer-Petersen, followed up series of "apical phthisis," some treated, others untreated.

—	Cases.	Progressive.	Per cent.
Braeuning	165	12	7·2
Lydtin..	450	31	7·0
Redecker and Walker	144	8	7·0
Kayer-Petersen ..	679	51	7·6
Total	1438	102	7·0

These figures show that only 7 per cent. of "apical phthises" became progressive pulmonary tuberculosis. This suggests that the spread from the apical region is uncommon. So far there are no figures to show how often "early infiltration" spreads to involve the apical region, but the facts known—i.e., (1) that the early infiltration is a rapidly progressing lesion, and (2) that many cases of extensive unilateral pulmonary tuberculosis give a short history—suggest that these cases have started as an "early infiltration," which is usually found in the infraclavicular region.

My best thanks are due to the honorary staff of the City of London Hospital for Diseases of the Heart and Lungs, for their kind permission to use these notes and diagrams of their cases.

"EPIDEMIC HICCUP."

By A. SALUSBURY MACNALTY, M.D. OXF., M.R.C.P. LOND.,

A MEDICAL OFFICER OF THE MINISTRY OF HEALTH.

THE occurrence of a number of cases of epidemic hiccup in this country during the first two months of the present year may make the following communication of interest, inasmuch as the malady is of comparatively recent recognition and perplexing to those who encounter it for the first time.

Symptomatology.—On Jan. 31st, 1929, at the request of Dr. Crewdson Thomas, I saw A. B., aged 57, a retired Army officer.

On Jan. 25th, after a journey to Liverpool, he contracted a cold and felt feverish and ill. He went to his office in the city on the 28th, but returned home at midday with a temperature of 100·2° F. Dr. Thomas saw him and ordered him to bed. On the following day the patient began to hiccup. The hiccuping was almost incessant; at intervals short intermissions occurred in which the patient lay back on his pillow in an exhausted condition. The attack lasted two and a half days and left the victim extremely weak. The pulse was slow, 56; the knee-jerks slightly exaggerated. There were no other signs on physical examination, except those of nasopharyngeal catarrh which rapidly cleared. The patient informed me that he had suffered from a similar attack, but of slighter severity, seven years previously.

This is a description of a fairly typical case of epidemic hiccup. The illness begins with a mild feverish attack of nasopharyngeal catarrh which may simulate "influenza" or a "cold in the head." There is usually some elevation of temperature and the pulse-rate is slowed. From 25 to 48 hours after the onset the patient is suddenly seized with a persistent rhythmic hiccup which continues incessantly all day, interferes with talking and eating, occasionally causes vomiting, and ceases only when the patient succeeds in obtaining sleep. The cerebro-spinal fluid is normal. The illness is usually mild although its subjects naturally suffer much inconvenience and some mental anxiety. The duration is usually from 24 hours to two or three days; the attack may last as long as a week, and Economo has described an exceptional case which endured for a whole month, the patient having only a few hours' respite each day. The nasopharyngeal catarrh subsides with the cessation of the characteristic attacks of hiccup. As a rule, there is complete recovery from the attack and an absence of complications or sequelæ. Courtois Suffit, however, in 1920 had under observation a patient suffering solely from hiccup who died in 48 hours.

One may fairly describe a case as one of "epidemic hiccup" from its clinical characters, just as one may diagnose a case of "epidemic encephalitis" without necessarily having evidence, in the particular instance, of a chain of infection, or even of the incidence of other similar cases in the neighbourhood. The conception of epidemic hiccup, epidemiologically, is similar to that of various epidemic diseases of the nervous system; thus while associated groups of cases or definite epidemics sometimes come to light, the ordinary train of evidence is that only here and there does the widespread infecting agent find an individual who reacts with an unmistakable illness manifested by a characteristic syndrome. Alternatively, the agent may infect the individual with such a massive dose, or in such a special manner, that the characteristic illness is produced. In other words, for every definite and characteristic case there is a large and indeterminate number of people who receive and carry the infection without themselves suffering noticeably, or at all.

This epidemiological concept results from the experience of previous appearances of epidemic hiccup, as well as of apparently "sporadic" cases.

Previous Appearances of Epidemic Hiccup.—In the autumn of 1919 small outbreaks of illness occurred in Egypt, Austria, Italy, Germany, and Canada in which hiccup, sometimes associated with fever, was the predominant symptom. An outbreak occurred in Vienna in January, 1920, and was described by Economo.[1] In the same month small epidemics were seen also in France[2] and in Switzerland. In December epidemic hiccup was common in Paris, and it was estimated that there were 5000 cases in the city. Railliet saw 130 cases in November and December in Rheims, and an epidemic which is said to have affected 500 persons occurred in the Bernese Jura in December and January, 1921. The disease was made notifiable in Switzerland, where 64 cases were notified. A few cases were reported in Canada, Australia, the United States, Denmark, and Norway.

In December, 1920, the disease was first noted in England, in London, Birmingham, Maidenhead, Oxford, Abingdon, and elsewhere. On behalf of the Ministry of Health I inquired into a group of 12 cases which occurred among the out-patients at Charing Cross Hospital.[3] None of these cases returned for treatment, which suggested that the attack was not one of long duration.

Since 1920 attacks of epidemic hiccup have occurred in the winter months of the year. In the first quarter of 1924, when encephalitis lethargica was prevalent, epidemic hiccup was widespread.

Age and Sex.—No complete statistical figures are available, but clinical experience and published reports lead one to the belief that males over 40 years of age are usually the subjects of the malady. In the Rheims outbreak it was definitely stated that children were not affected.

Infectivity.—Epidemic hiccup is an infectious disease although the degree of infectivity is not high. In two instances in Paris two bank clerks occupying the same desk were almost simultaneously affected. In the London outbreak of 1920 the casualty medical officer of Charing Cross Hospital apparently contracted the disease from his patients. Several instances of multiple cases of epidemic hiccup in households were seen in 1921.

Relation to Encephalitis Lethargica.—Economo[1] recorded hiccup as a complication of encephalitis lethargica in 1917, and I noted it in five of my series of cases in 1918.[5] About a month after the first appearance of epidemic hiccup in Vienna (1919–20) a myoclonic form of encephalitis was seen in which clonic convulsions and hiccup were followed by choreic movements. Economo wrote at that date:—

> "It is not possible to say that the epidemic of hiccup was already a precursor of this encephalitis with a particular localisation in the region of the phrenic vagus, but future observations on the possible relationship will be worth noting."

Staehelin[6] reporting on an epidemic at Gerlafingen in Switzerland, states that the sequence of events was first an epidemic of transitory ocular paralyses, then an epidemic of hiccup, and finally many cases of epidemic encephalitis. From observations on French cases Dufour,[7] Renard and Netter[8] definitely considered that epidemic hiccup is a masked form of encephalitis lethargica.

The English experience is in accordance with this view. The late Dr. Farrar reported the following instance of probable association between epidemic hiccup and encephalitis lethargica at Birmingham.

> "Mr. P., senior, aged 65, visited his son, Mr. G. P., aged 30, on Dec. 16th, 1920. Between Dec. 20th and 25th, Mr. P., senior, had a violent paroxysmal hiccup which lasted a week and left him quite exhausted. On Dec. 27th—i.e., 11 days after seeing his father—Mr. G. P. developed typical encephalitis lethargica with myoclonic twitchings, but no hiccup. On Jan. 6th, 1921, Mr. G. P. was visited by his brother, Captain P., and assisted to fit a water-bed. A few days later Captain P. had a severe attack of hiccup lasting for four days."

In the widespread epidemic of encephalitis lethargica in 1921, in which 5039 cases with 1410 deaths were recorded in England and Wales, epidemic hiccup was also widely prevalent and was seen in definite association, for instance in the same household, with encephalitis lethargica. Sir John Robertson, then medical officer of health for Birmingham, from his experience in the Birmingham epidemic, was strongly of opinion that epidemic hiccup may be a symptom of encephalitis of a mild type. There is therefore good reason in view of the cumulative evidence for regarding epidemic hiccup as a mild or frustrated form of encephalitis lethargica. If the identity of the two forms of disease is accepted, although the illness is temporarily exhausting and distressing, the speedy recovery and the absence of after-effects decidedly make epidemic hiccup the form of encephalitis lethargica which it is most desirable to suffer from.

Diagnosis.—The causes of persistent hiccup are manifold, but the association of hiccup of sudden onset with an elevation of temperature, antecedent nasopharyngeal catarrh, and frequently a slowed pulse-rate makes the disease usually quite recognisable. Subdiaphragmatic conditions, pleural and phrenic irritation by new growths, and central causes have to be excluded. Of central causes the persistent hiccup of uræmia and that due to cerebral irritation set up by a tumour or hæmorrhage may be instanced. It must not be forgotten that epidemic hiccup is most likely to be mistaken for the hiccup which is a pure functional manifestation, especially when the patient is a nervous individual.

Treatment.—C. F. T. East[9] gives a long list of remedies for persistent hiccup. In practice it is usually found that epidemic hiccup must run its course, and that attention has to be devoted to making the patient as comfortable as possible, and to assuring him that the attack, although troublesome, is not dangerous and will be of short duration.

In the severe cases the patient should be confined to bed. Sedatives, such as bromides, may be given; and occasionally relief is experienced when belladonna or cajuput oil is administered; if the paroxysms of hiccuping greatly distress the patient and prevent him from sleeping, morphia combined with atropine may be efficacious in steering him through the illness.

Clinical and Laboratory Notes.

A CONGENITAL SOLITARY KIDNEY.

By Albert Sharman, B.Sc., M.B. Glasg.,

LATE RESIDENT SURGEON, ROYAL ALEXANDRA INFIRMARY, PAISLEY; EXTRA-SURGEON, OUT-PATIENT DEPARTMENT, ROYAL SAMARITAN HOSPITAL FOR WOMEN, GLASGOW.

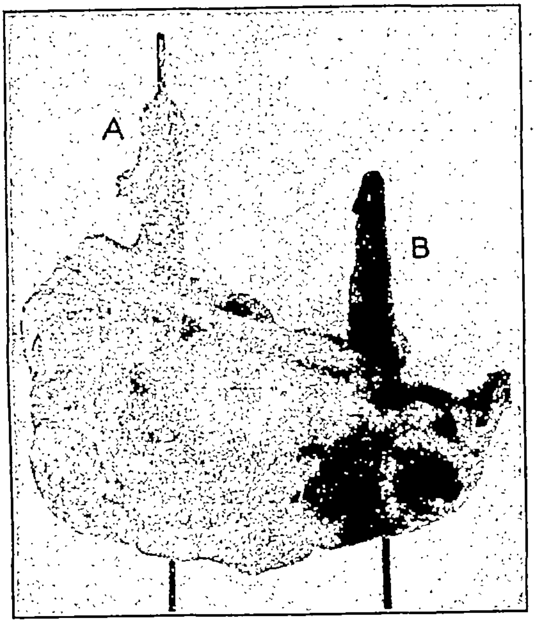
Congenital absence of one kidney is uncommon, the incidence at autopsy being about 1 in 1610 cases, according to the most recent figures of Campbell.[1] About 400 cases have been reported in all; 280 were described before 1910, since when Anders[2] has added 61, Eisendrath[3] 25, and Campbell[1] 9. The condition is generally found at post-mortem examination, but 31 clinical cases have been collected, only some of which have been confirmed by subsequent autopsy. In Campbell's series the youngest patient was 5 days, and the oldest 60 years of age.

The single kidney is most often the right, and its form varies little from the normal except when it is ectopic. It is often hypertrophic, sometimes normal in size, and in about 5 per cent. of cases very small.[4] The course and ending of the ureter of the solitary kidney may vary from the normal; in some cases it opens in the midline of the bladder, and, rarely, crosses the midline to end in the opposite side of the bladder (Eisendrath). The ureter on the opposite side to the one where the solitary kidney is situated is generally absent, but may vary from a shallow pouch or cul-de-sac to one which is patent for about half the length of the normal ureter. Among 61 cases, Anders[2] found a more or less patent ureter in 10; Winter[5] found this in 18 cases out of 237; and Eisendrath quotes three cases in which the ureter was patent for 1 cm., 8 cm., and 3 cm. respectively, and also Thevenot's case where it was patent for 15·2 cm.—i.e., for half its normal length. Instead of the rudimentary ureter ending at the normal ureteral orifice, however, abnormal extra-vesical endings may be met with. Papin[6] quotes five cases in which there was reduplication of the pelves and ureters of the solitary kidney. The adrenal is sometimes absent on the involved side. Various associated genital defects are occasionally met with—for example, unilateral absence of seminal vesicle or vas deferens, abnormality or absence of uterus, or rudimentary development of vagina. The solitary organ is said to be specially liable to be attacked by disease. Hannay and Young reported a case of carcinoma of a solitary kidney.[7]

The fact that the condition is rarely discovered before death, especially by exploratory laparotomy, prompts me to record this additional case, which has features of much interest.

The Case Described.

A married woman, aged 26 years, was admitted to the Royal Alexandra Infirmary, Paisley, under the care of Mr. Hugh Donald, and complained of severe pain of 24 hours' duration in the right side of the abdomen. She stated that five days before admission she had had an attack of shivering, felt out of sorts, and had some pain and tenderness in her "appendix region." She remained in bed and the pain passed off until the onset of the severe attack, which compelled her to send for the family doctor, who diagnosed the condition as "appendix abscess." For about six years previously she had had occasional attacks of right-sided pain, accompanied by nausea and vomiting, and always relieved by lying down. For as long as she could remember she had had frequency of micturition, but had never complained of it.



Interior of the bladder with probes in the ureteric orifices. A = right ureter. B = left ureter (blind).

On admission her temperature was 103·8° F., pulse-rate 144, and respiration-rate 24. A large tumour was definitely palpable and tender to the right of the umbilicus, and extended from about an inch above the umbilicus to almost the level of the anterior superior iliac spine. There was very great tenderness over McBurney's point. Examination of urine showed a specific gravity of 1018, a neutral reaction, and the presence of distinct albumin, pus, and blood. The diagnosis of large appendix abscess was questioned, but it was decided to do a laparotomy. The abdomen was opened through a right rectus incision, and the tumour was found to be a large distended right kidney sac. The left kidney was then sought—a comparatively easy procedure through this incision—but to our great surprise could not be found. Its absence was corroborated by the assistant surgeon. The right renal pelvis was aspirated at two separate points but no purulent fluid was obtained. It was not deemed advisable to interfere further, and the abdomen was closed.

In the succeeding 24 hours the patient passed 4 oz. of urine, and in the next day 6 oz. Forty-eight hours after operation she was catheterised, but no urine was obtained from the bladder, and there was complete anuria until death, which occurred 66 hours after operation. Two hours before death 1¼ oz. of pus was passed per urethram. Post-mortem, catheterisation failed to find urine in the bladder. The post-operation urine was examined by the pathologist to the infirmary, Dr. M. B. Hannay, who also conducted the post-mortem examination.

Report on urine.—Amber, very turbid, alkaline, specific gravity 1010. A very large amount of albumin (1·8 per cent.) is present. The cell deposit is very large in amount and consists of pus. Microscopically, in addition to pus, there are frequent red blood cells and a few epithelial cells and micro-organisms. A Gram film shows numerous coliform bacilli, and culture gives a growth of *Bacillus coli*.

Post-mortem report.—The right kidney weighs 23 oz., and is displaced downwards. It measures 6½ by 3 by 2¾ in., and is thus greatly enlarged (normal is about 4 by 2½ by 1¼ in.). It is very soft, and shows areas of congestion. The renal pelvis is much dilated, to the size of a hen's egg, and contains pus. The walls are not noticeably thickened. The right ureter is thin-walled and dilated below. At the upper end, which is of the normal width, there is a kink caused by the dropping of the enlarged kidney. There is no trace of the left kidney. The left ureter ends blindly, 2½ in. (6·3 cm.) from the bladder. There is no scar in the left loin. Both adrenals are present and normal. There are no genital defects. The cause of death is acute cystitis and pyelonephritis.

The photograph shows the interior of the bladder with probes in the ureteral orifices, the one on the left side passing up the right ureter, which has been cut across, and the one on the right side lying in the blindly ending rudimentary left ureter.

Comment.

The only case found in the literature resembling this is that of Winter,[5] in which the pre-operative findings were "sudden onset, large right abdominal tumour, and no cystoscopy. Exploratory operation revealed a large cystic kidney, which was removed. Autopsy five days after operation revealed a left ureter 8 cm. long, ending normally below, but blindly above. The left kidney was absent."

There are six instances in the literature, quoted by Eisendrath,[3] of congenital single kidney in which nephrectomy was performed on the solitary kidney, unwittingly, for tumour, severe renal infection, or tuberculosis.

My case is a warning to all who contemplate any kind of surgical interference in renal disease without catheterisation of the ureters. The possibility of *unilateral kidney should be kept in the forefront of a* surgeon's thoughts when called to perform a nephrectomy, especially when the loin incision is employed. It should be a rule never to remove a kidney without previously having made certain of the presence of a second and, apart from opening the abdominal cavity, the only method is by pyelography. This is Galbraith's[8] view, and he adds that cystoscopy showing the normal excretion of indigo-carmine from a normally placed ureter may be fallacious. Russell Howard[9] states that if one kidney is absent the opening of the ureter into the bladder is also absent, and the condition may be recognised on cystoscopic examination. This is erroneous, as is the similar statement of Thomson and Miles[10] that congenital absence of one kidney presents, on cystoscopic examination, only one ureteral orifice.

The appearance of two normally situated ureteral orifices on cystoscopy is not necessarily indicative of the presence of two kidneys, as my case of patent rudimentary ureter emphasises.

I wish to thank Mr. Hugh Donald for permission to publish this case, and Dr. Mary B. Hannay, to whom I am indebted for the pathological reports and photograph.

HYPOPYON ULCER OF THE CORNEA.

A BRIEF REVIEW OF ONE HUNDRED CONSECUTIVE CASES.

BY A. CHRISTIE REID, M.D. ABERD.,
HON. SURGEON TO THE NOTTINGHAM EYE INFIRMARY.

THE object of this article is threefold: (*a*) To impress on the practitioner that any corneal ulcer with pus in the anterior chamber is threatening an eye; (*b*) to supply figures for comparison with new methods of treatment; and (*c*) to commend early opening of the anterior chamber by a special incision.

These ulcers vary much in severity in different countries and in different parts of the same country. Of my cases 60 were miners working below ground;

these represent a type generally severe. In only one case—and he not a miner—was a foreign body present in the ulcer. I have not known such an ulcer to follow extraction of a foreign body in our casualty department where we deal with some 2800 foreign bodies per annum. Nine cases were women; only one was a child, aged 2, which cleared well with lotion and atropine only. Several cases presenting late or in debilitated or aged persons were doomed from the start, but these have been included, though for statistical purposes they are not of much value. The 100 cases range over six years and all were hospital cases.

Methods of Treatment.

Treatment has varied somewhat, but the following methods have been tried out and are now more or less stereotyped as follows: (*a*) Rest in bed, as flat on the back as possible, for at least 5 days and often for 15. Too early assumption of the erect posture, and too prompt dismissal from the ward, has been too often followed by recurrence. (*b*) Atropine drops and frequent lustrations even to the intensive half-hourly method recently advocated, if this can be carried out. (*c*) A search is made for septic foci elsewhere—e.g., teeth and tear sac—and, if possible, these are dealt with. (*d*) Carbolisation with pure carbolic unless the cornea is deeply infiltrated. If the case is only seen after the fifth day this often does more harm than good. Actual cautery, even by chauffage, I have found to produce a very dense but soft scar; but I confess to not having adopted the carefully graduated method of Mr. Edgar Stevenson, of Liverpool. (*e*) General tonic treatment, and more recently sodium salicylate intravenously. (*f*) Section. As it is more especially this last I wish to advocate, I shall briefly describe my method.

Under (local anæsthetic) cocaine a small keratome incision just inside the limbus is made in lower part of the cornea into the anterior chamber. A modified Usher's spatula is then introduced, and on to it with a special semi-circular knife (like an old-fashioned vaccination lancet) a vertical incision is made through the corneal substance, thus completing an inverted T. *Both instruments are made by Messrs. Down Bros. and* Weiss and Son. The first incision is best done facing the patient, the second from behind. Thus the lens is protected and complete control of the eye obtained by the spatula. The second incision may require two or three to and fro movements of the knife, but may be done by one sweep from centre to periphery. The advantage of this incision is not only its completeness but its accessibility for subsequent tappings if deemed necessary. The point of the crossing is easily made out even weeks after, and I have with the greatest ease broken in with a blunt instrument 12 days after the original incision. Evacuation of the pus is not essential; it sometimes flows freely, at others is sticky and thick. It should not perhaps be left in the wound as it is then likely to act as a wick to introduce infection. One, two, or more subsequent tappings at intervals of two or three days may be indicated.

Results of Early Section.

Results of treatment may be considered statistically, but if so, great reserves must be made as there are many varying factors.[1] Thus 63 of my cases were sectioned, but I do not advocate section in every case, though I have never regretted an early section. *And the fact that of 37 cases not sectioned 30 did* well—result "good" or "fair"—does not prove anything against section, because most of these cases were of a mild type. Of the 37 non-sectioned cases 27 were good, 3 were fair, 7 were bad, and none was "lost." Six of the bad were cautery cases which perforated.

My sectioned cases fall into two groups—(*a*) those done before the fourteenth day from the date of onset, usually a trauma; (*b*) those on the fifteenth day or later. Of (*a*) 3 were lost, 11 bad, 5 fair, 14 good, total 33. Of (*b*) 6 were lost, 12 bad, 5 fair, 7 good, total 30. *Thus 9 eyes out of the 100 were lost*; but statistics of removal depend largely on the personal factor. I endeavour to retain an eye if it has only P.L. (perception of light) and is not painful. Unsightliness does not weigh heavily.

The better results of the early-sectioned cases are enhanced by a closer study of the failures, but space does not allow of that here. In two of these latter *the damage seemed to be done by a plastic iritis quite* different from the simpler cyclitic hypopyon. All other methods of treatment seem ineffectual in such cases, and section is the only means I know of that has in one or two caused definite arrest of the process, even when done late.

But the time factor is not everything. Some cases, for example, show very extensive or deep ulcer only three or four days after onset; these are virulent, but many of these may be saved by prompt section. On the other hand, a fair proportion of late cases that had run a mild but chronic course were sectioned after all other means had failed, and this brought about definite arrest with a good visual or scar result.

The terror of the Guthrie-Saemisch section with its adherent iris is done away with by this innocuous yet efficient section. An adherent iris is a rarity and usually due to an error in technique or the presence of a plastic iritis that would have blocked the pupil in any case. In only five cases of the series did lens opacity result. In two of these the patient jibbed badly, and it is possible that with the dilated pupil of atropine the point of the keratome may have touched the lens. I think, however, that the presence of semi-solid pus lying for weeks, it may be, on a segment of iris and lens, may in itself, apart from any error in technique, cause some localised lens opacity that may later involve the whole lens.

Finally, I would urge that it is not on account of plus tension that section is undertaken. Renewal of aqueous is the vital necessity. A by-effect may be the lowered corneal tension allowing healing lymph to pass more freely through the corneal tissue. The two flaps of the section have at times been noted as definitely œdematous. Plus tension may occur, but in my experience is a late phenomenon. Two of my obstinate cases had a definitely minus tension—one was sectioned, the other not; both did well.

Can one, then, lay down a definite line of treatment in hypopyon ulcer? I am afraid not. The cases are polymorphic. Space does not permit a closer analysis of types. No allusion has been made, for instance, to the diplobacillary type to which two in my series seemed to belong. Whether localised ultra-violet rays will replace present methods remains to be seen. London and Toronto statistics of hypopyon ulcer must be accepted with caution. A total of 48 "good" results in these 100 cases, of which 21 were sectioned and 27 not, may or may not be regarded as satisfactory.

AN UNCOMMON ABDOMINAL CYST IN A YOUNG CHILD.

By A. H. D. Smith, *M.C.*, M.B. Edin.,
HON. SURGEON TO THE LLANELLY GENERAL HOSPITAL.

The comparative rarity of cysts of the omentum encourages me to record a case which has recently passed through my hands. The only detailed account of omental cysts I have been able to find is in Keen's "Surgery" (Vol. IV., pp. 632 and 633). Here it is stated that cysts of the omentum are most frequently seen in children under 10 years of age, 50 per cent. being under 10, and 65 per cent. under 20 years of age; 75 per cent. of cases occur in females.

The patient was a healthy boy of 4, who had had an uneventful medical history. His parents were both healthy, and he had been perfectly fit until a fortnight before I saw him. His mother had then observed a swelling of the lower abdomen which had rapidly increased in size, and she had called in Dr. Hugh John of Llangennech to see him. While attended by Dr. John, the boy had complained of vague abdominal discomfort. On one or two occasions there had been a rise of temperature to 100° F., and on one occasion a little blood had been passed in the urine.

---

[1] Results from the visual and scarring point of view may be tabulated as: "good" = 6/6 to 6/18 or very slight scar; "fair" = 6/18 to 6/60 with denser scar; "bad" = less than 6/60 or very dense scar; and "loss of eye" cases.

Dr. John asked me to see the boy with him on April 7th. I found a slightly-built, well-nourished boy, who complained of slight abdominal discomfort. The abdomen was much swollen in the lower part. The pulse and temperature were normal. A hard tumour was felt, filling the abdomen below the umbilicus. The bladder was empty, and there was a distinct gap between the tumour and the pubes. The tumour seemed to fill up the pelvis. There was no distension of the abdominal veins. In view of the rapid growth it was thought that the condition might be due to a malignant growth of the kidney (particularly in view of the history of hæmaturia on one occasion). Encysted tuberculous ascites was also considered, as were retroperitoneal growth and various congenital cystic conditions. Laparotomy was advised and later performed under general anæsthesia.

The abdomen was opened by a mid-line incision, extending from the umbilicus to the pubes. On opening the peritoneum a large mass was seen, adherent by very easily separated adhesions to the peritoneum of the anterior abdominal wall. After separating the adhesions, the tumour was found firmly adherent to the omentum. The attached omentum was clamped and ligated, and the tumour found almost completely to fill the pelvis. So slight were the adhesions to the peritoneum of the pelvic floor that during the process of examining the posterior attachments of the growth the tumour separated away completely from them, leaving a few very small bleeding points, none of which needed ligation. The abdomen was closed and the wound healed by primary union, the patient leaving hospital 12 days later.

The tumour was about the size of the head of a six-months-old child. It was polycystic, and attached to it were several smaller cysts. All the cysts were opened and were found to contain a clear substance, of the consistency of jelly which had only partially set, and a certain amount of fluid like blood serum. There was no blood. The cyst wall was sent to Dr. S. C. Dyke, consulting pathologist, the Royal Hospital, Wolverhampton, who has sent me the following report:—

"The portion of cyst wall consists of fibrous tissue only. This fibrous tissue is very dense in some parts; in others the cells are vegetative in type and show evidence of rapid recent growth. The fibrous tissue contains well-formed blood-vessels and some included groups of fat cells. Inflammatory cells are present but not in very large numbers, certainly not in sufficiently large numbers to suggest an inflammatory origin for the cyst. These cells are of all types: polymorphonuclear leucocytes, eosinophiles, and plasma cells. There are also a few collections of large mononuclear cells apparently derived from the lining of the omentum. I think it is possible to say with certainty that this cyst is not neoplastic, and there appears to be no reason why it should recur after having been completely removed. It can only be described as an omental cyst. Such cysts are rare but they do occur. On preliminary examination of the specimen my first impression was that you had sent me the wall of an hydatid cyst. The specimen would pass as the ectocyst, but there is no trace of endocyst. This lies under the ectocyst and is translucent and gelatinous. I presume that I am justified in believing that no such endocyst existed. I think you are justified in telling the relatives that it will not recur. Certainly it is not malignant."

The chief interest in this case lies in the fact that the condition is rare, and does not seem to attract the attention it should in the differential diagnosis of abdominal tumours in children. In the case described there was no endocyst, and it will be interesting, in view of Dr. Dyke's report, to follow the future medical history of this child. The condition can, I think, only be diagnosed definitely by laparotomy, but it seems to me one which must be thought of in the diagnosis of abdominal swellings in children.

BIRMINGHAM HOSPITAL SATURDAY FUND.—During the first half of the present year 4500 employees of 285 contributing firms have joined the Fund, and £20,000 has been handed to the contributory scheme as against £15,000 for the corresponding quarter last year. The convalescent home accommodation of the Fund is so seriously overtaxed that there is a waiting-list of 1146 cases. There is still a debt of about £27,000 upon the building fund of the Tyn-y-Coed Home, and a large number of firms are subscribing an additional penny per head per week towards reducing it.

Medical Societies.

PATHOLOGICAL SOCIETY OF GREAT BRITAIN AND IRELAND.

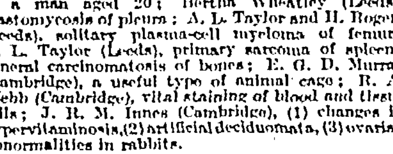
A MEETING was held in the new institute of pathology in Tennis Court-road, Cambridge, on July 5th and 6th, with Prof. H. R. DEAN, Master of Trinity Hall, in the chair.

C. H. Whittle (Cambridge) in the course of many tests of pneumococci on mice had found that about 2 per cent. of the animals developed a pneumococcal otitis media with rotary and other movements and might die from a secondary pneumococcal septicæmia.—A. D. Gardner (Oxford) had watched the multiplication of the tubercle bacillus and found that it followed ordinary lines; he saw nothing suggestive of a granule phase or any complicated life-history.—F. W. Andrewes (London) noted that a few strains of hæmolytic streptococci actively fermented starch and gave an elegant demonstration of the reaction.—T. J. Mackie, D. G. S. McLachlan, and E. J. N. Anderson (Edinburgh) had isolated the tetanus bacillus from a specimen of catgut supposed to be implicated in an outbreak of post-operative tetanus. Catgut artificially contaminated with spores infects guinea-pigs experimentally, the spores washed off it do not, nor do spores injected into the neighbourhood of implanted catgut. Sublethal doses of *B. welchii* make tetanus spores effective and exposure of animals to cold eight weeks after inoculation of spores may determine a fatal tetanus.—C. H. Andrewes (London) showed that virus III. developed the characteristic inclusion bodies in cultures of rabbit testis and with the same technique showed that the resistance of immunised animals depended on the blood plasma rather than the tissue cells.—S. P. Bedson (London) proved that it was possible to immunise guinea-pigs against herpes and cause the production of neutralising antibody in the blood by formalin-killed virus.—J. Craigie and W. J. Tulloch (Dundee) showed how specific and valuable was the flocculation test (rabbit immune serum and extracts of vesicles) in the differential diagnosis of small-pox and that it could not well be due to contaminating bacteria as has been supposed.—H. R. Dean, N. E. Goldsworthy, and C. TenBroeck (Cambridge) discussed the technical difficulties in measuring the rate of disappearance of horse serum injected into the blood of rabbits.—W. W. C. Topley and G. S. Wilson (London) starting with Schütze's discovery that *B. pseudotuberculosis* and *B. aertrycke* had a common O heat-stable antigen failed to protect mice against *aertrycke* with pseudotubercle vaccines but got passive protection with immune rabbit sera.—J. Craigie (Dundee) detailed his experiments on the flagella and somatic antigens of the typhoid bacillus.—J. Gordon (Leeds) found that dyes of the congo-red group interfered with hæmolysis and bacteriolysis.—E. G. D. Murray (Cambridge) dealt with the technique of standardising dysentery antitoxin.—C. H. Browning and R. Gulbrausen (Glasgow) showed how the immunity developed by the stimulation of dead parasites was a factor in the curing of trypanosome infections by chemotherapeutic agents.—W. T. Hillier (Birmingham) described the determination of red cell fragility and its application in the differential diagnosis of jaundices.—J. Davidson (Edinburgh) examined the action of senecifoline (from ragwort) on the rat's liver: it causes hæmorrhage, acute necrosis, proliferation of kupffer cells, and finally in surviving animals fibrosis and cirrhosis.—J. H. Dible (Liverpool) showed that the amount of fat which accumulates in the liver during starvation depends on the abundance of storage fat in the body.—W. Cramer (London) detailed further experiments showing how the development of one tar cancer tends to inhibit the appearance of another.—T. Hare (London) described a case of spondylitis deformans in a dog associated with advanced general arterio-sclerosis and discussed the possibility of the primary periarticular lesions being due to arteriolar damage.—Norah H. Schuster (London) dealt with the classification of lung tumours especially with the possibility of recognising those arising in the alveoli.—H. L. Sheehan (Manchester) described a remarkable cystic tumour of the liver in a child, including connective tissue, epithelial tubes, and striped muscle, and concluded that it was a mesoblastic hamartoma in which both mesenchyme and mesothelium were represented.—J. Braxton Hicks (London) described a congenital deficiency of the œsophagus and a case in which more than 300 cysticercus cysts were found in the brain.—Among the demonstrations were the following: R. H. Morley, acute miliary tuberculosis in an infant of six weeks with older lesions in the liver suggesting intra-uterine infection; A. N. Drury (Cambridge), a substance isolated from normal heart muscle which causes experimental heart-block; E. W. Hurst (London), lesions of experimental poliomyelitis in monkeys; C. H. Whittle (Cambridge), cor bovinum in a man aged 20; Bertha Wheatley (Leeds), blastomycosis of pleura; A. L. Taylor and H. Rogers (Leeds), solitary plasma-cell myeloma of femur; A. L. Taylor (Leeds), primary sarcoma of spleen; general carcinomatosis of bones; E. G. D. Murray (Cambridge), a useful type of animal cage; R. A. Webb (Cambridge), vital staining of blood and tissue cells; J. R. M. Innes (Cambridge), (1) changes in hypervitaminosis, (2) artificial deciduomata, (3) ovarian abnormalities in rabbits.

New Inventions.

A BONE-RETAINING CLAMP.

THE instrument here illustrated is intended for use in operations upon oblique fractures of long bones, especially the femur and the humerus. The fragments are manipulated into perfect coaptation in the usual way, with long bone-holding forceps, and the encircling clamp is then applied. If the fracture be of the long, oblique variety, two can be used, and retention is then perfect without the need of any other intervention by means of forceps, &c. The clamp has been devised to overcome some of the difficulties that are commonly met in the use of existing types. It is often found that the handles of these clamps are very much in the way in the wound; either they have to be released in order to get the plate into position or, as they can only be applied in one plane, they are not suitable for use in many cases of oblique fracture. The new clamp, the handle of which is detachable, occupies very little space in the wound and it can be applied at almost any angle, according to the direction of the fracture. Even when one only can be used, it so far steadies the fragments that they can be held firmly in position by one assistant with very little effort.



The clamp is made of stainless steel, in two sizes, by Messrs. Allen and Hanburys, Ltd., Wigmore-street, *London*, W.

ALAN H. TODD, M.S. Lond., F.R.C.S. Eng.

OXFORD OPHTHALMOLOGICAL CONGRESS.

DISCUSSION AT THE ANNUAL MEETING.

THE sixteenth annual meeting of this Congress was held at Oxford from July 4th to 6th, with Mr. A. BERNARD CHIDLAND, the Master, presiding. It was very largely attended.

On Thursday, after a short address of welcome by the Master, a discussion on

Diseases of the Lacrymal Apparatus

was introduced by Prof. JOSEPH MELLER (Vienna). In the course of his paper he discussed the frequency with which stenosis led to epiphora. Examination of a large number of cadavers, he said, showed that the lacrymal canaliculi were normal in only 80 per cent. It could be stated that most lacrymal passages were more or less diseased, but without conjunctivitis. Most of the subjects of diseased passages were women. X rays afforded the first means of satisfactorily seeing the normal and pathological conditions of the sac in the living person. Often, too, X rays would give an indication of the kind of operation required. Radium applied to a tuberculous condition of the tear sac gave very successful results, so that operation was rendered unnecessary. Many ophthalmologists made the mistake of regarding epiphora as synonymous with stenosis of the lacrymal duct. Slitting of the canaliculi was now less often performed than formerly; and in all cases the operator must avoid slitting the canaliculus as far as the canthus. For dilatation of the tear-duct the permanent probe treatment seemed to have been abandoned.

Turning to the local treatment of chronic dacryocystitis with more or less copious secretion Prof. Meller said the condition could occasionally be favourably influenced, even cured, by medical means. Silver nitrate in ¼ per cent. solution, applied with the syringe, seemed best. Tincture of iodine had been used for the purpose, but it caused considerable irritation of the conjunctiva. After a properly performed extirpation of the sac, the epiphora, which before the operation was copious, almost always became so slight that the majority of the patients made no further complaint of it. If, however, a small particle of mucous membrane was left behind, lacrymation continued, and might be as severe as before the operation. There had been a good deal of discussion as to whether, after the canaliculi had been slit in Toti's operation, the normal conveyance of tears was or was not restored. It was now recognised that intact canaliculi were not absolutely essential. Notwithstanding slit canaliculi, the epiphora ceased completely after the operation. Koller's trans-septal procedure had increased the view of the field of operation, so that every step of it was carried out under visual control. The operation was performed painlessly under local anæsthesia, and the results were excellent, even in elderly people. Prof. Meller advised ophthalmic surgeons, in cases of dacryocystitis in which operative interference was indicated, to extirpate the sac; a good extirpation was, he said, better than a poor dacryocystorhinostomy.

Mr. J. S. FRASER (Edinburgh) treated the subject from the standpoint of the rhinologist, entitling his paper Intranasal Dacryocystotomy. His contribution was based upon 99 patients, 90 of whom had a diseased condition on one side only. The total number of operations done on them was 108. Most of them had already been seen by an ophthalmic surgeon before they came to him. In 80 of the cases he was able to keep track of the patients subsequently, and 67 of them were regarded as completely successful—i.e., there was no recurrence of swelling in the tear sac, no pus could be squeezed out, and the eye did not water. The patients' only comment was that occasionally when they blew their noses they blew their eyes also. The most successful results were obtained in cases in which there was a definite collection of muco-purulent fluid in the tear sac. If he had tried to get patients to undergo operation two or three times doubtless he would have obtained a better figure than 75 per cent. of cures.

Mr. T. HARRISON BUTLER (Birmingham) said he did not use a retractor when operating on these cases. He had had only four or five cases of troublesome epiphora after operating, and in most of them, on reopening the cavity, he had found a relic of mucous membrane. On removing this, the epiphora ceased. A very serious possible complication was ulceration of the cornea from accidental injury during the operation. He related two such cases.

Mr. E. D. D. DAVIS (London) gave a short review of the subject from the rhinological point of view, instancing cases in illustration, and demonstrating a series of slides.

Dr. S. H. BROWNING (London) spoke as a bacteriologist. He had a good word to say for optochin in pneumococcal infections, which were common in the lacrymal sac; this remedy must, however, be used freshly prepared and with discrimination. He referred to the frequency with which streptothrix infections of the canaliculi existed and were missed. Patients who had these infections usually were found to have to do with horses, and the infection was probably derived from dried horse manure.

Mr. D. LEIGHTON DAVIES (Cardiff) said he did not regard a patient who had had West's operation done on him as cured unless he was well three months afterwards. Though it could be guaranteed that every patient would go out of hospital cured a month or so later contraction of the scar might set in; 24 of 38 of his cases since 1912 had been permanently cured. There was a group of cases in which no complaint of epiphora was made afterwards, but in which fluid could not be got through into the nose. These he did not regard as complete cures, and he had not included them as such. Toti's operation was, he considered, best suited for young people; he had ceased to do it on patients aged 58 years and over, as they were liable to hæmorrhages.

Mr. A. GREENE (Norwich) referred to the occurrence of epiphora without ascertainable cause, and asked whether excision of the lacrymal gland was frequently suitable for these. He did not think the nose operation was satisfactory for a diseased lacrymal sac.

On Friday the Doyne Memorial Lecture was delivered by Miss IDA MANN (London), under the title

Some Observations on the Vascularisation of the Vertebrate Eye.

The arrangement of the intra-ocular blood-vessels showed many remarkable variations, she said, in different species of vertebrates. If the subject was studied from the point of view of comparative embryology, it became possible, by investigating stages of development common to several dissimilar species, to arrive at a classification of adult types based on their mode of production. This classification did not entirely correspond with the usual classification of the vertebrates. Although in most animals one type of ocular vascularisation corresponded with one class of vertebrates, yet there were many instances of overlapping (as when the lower reptiles showed amphibian characteristics) and of convergence, in which a similar structure was found in two entirely unrelated species, for example, in snakes and in rodents. So far as was known, these exceptions could not be correlated with similarity in other respects, except, possibly, with similarity of visual acuity. For the purposes of discussion, Miss Mann divided the ocular vessels into three sets: those of the choroid, of the retina, and of the iris. In this lecture the choroidal vessels were not considered in detail. She showed that the variations in the retinal and iridic vessels depended, developmentally, upon modifications of the proximal and of the distal end respectively of the hyaloid artery, which was present in all vertebrates at some embryonic stage. Its proximal end might undergo four possible modifications, and these produced the four main types of retinal vascularisation. (1) Complete atrophy of the vessel produced an avascular retina nourished entirely by the choroid. (2) Vascularisation of the epithelial cells on the optic disc produced a pecten, a structure typical of the birds. (3) Branching of the hyaloid proximally in the vitreous produced a membrana vasculosa retinæ. (4) Branching of the hyaloid proximally in the retina produced the arteria centralis retinæ of the primates.

It could be shown that the presence of a pupillary membrane during development had a marked influence on the definitive iris pattern. Those mammals which possessed it showed, in adult life, two types of circulation in the iris: a direct arterio-venous anastomosis in the superficial layers, and a capillary circulation in the deeper parts. Animals not possessing a pupillary membrane showed only the capillary system, and in them, too, there was a much greater range of iris pattern.

Slit-lamp appearances of the iris in a variety of lower animals were shown. A very wide range of modification was possible, not only in pigmentation but also in the number and arrangement of the main arteries and veins, and in the width and richness of the capillary plexus.

Dr. T. A. POOLE (Washington) read a paper on the Effects of Disease of the Paranasal Sinuses upon the Fixation Point; Mr. N. C. RIDLEY (Leicester) one on an Unusual Complication of Hodgkin's Disease; and Mr. E. N. HUGHES (Liverpool) one on the Structure of the Vitreous. Colonel H. HERBERT (Brighton) contributed a paper on the Cement Substance of the Intra-ocular Muscles and Glaucoma.

A discussion on

Ocular Manifestations Found in Head Injuries

was opened by Mr. HUGH CAIRNS (London). In the past, he said, undue attention had been paid to the fracture of the skull which often followed a blow on the head. It was true that certain of the ocular manifestations of head injury, such as damage to the optic and abducens nerves, were produced by the fracture, but, as a general rule, the important element of a head injury was not the fracture of the skull, but the injury to the underlying brain.

The greatest surgical problem was to know which cases would benefit by operation. Some patients would inevitably die soon after the injury—such cases being seen in greater numbers as the speed at which people travelled increased. In other cases it was soon evident, after the concussion had passed off, that the injury was comparatively mild, and that with suitable conservative treatment the patient would recover. There remained a third group, in which the outcome was for a time uncertain. These comprised cases in which, after recovery from the initial unconsciousness and concussion, there was either a relapse into coma or alternating periods of stupor and lucidity; and cases in which concussion did not occur, and unconsciousness only came on at an interval of hours or days after the accident. In this group the symptoms were usually due to a rise of intracranial pressure as a result of intracranial hæmorrhage, or œdema of the injured brain, or disturbance of the circulation of the cerebro-spinal fluid. It was often very difficult to decide which were the cases that would benefit by operation. In arriving at a decision about this the patient's state of unconsciousness was the most useful guide. A blow on the head tended to damage the brain not only at the site of the impact, but also at other places, especially at the opposite side of the brain.

Slight blurring of the discs, continued Mr. Cairns, could be seen in many cases which at operation showed a large blood-clot, severe cerebral œdema, or a collection of cerebro-spinal fluid in the subdural space. In 80 cases of head injury which he had seen in civil life there were only seven of definite papillœdema. Another cause for the appearance of papillœdema after head injury was the collection of cerebrospinal fluid, often mixed with blood, in the subdural space. When papillœdema was present the patient should have operative treatment, even though at the time he might be relatively free from symptoms. A well-planned decompression would give the patient a much better chance of avoiding the chronic ill-health which otherwise so often followed head injury. Lateral deviation of the head and eyes towards the injured side was very important as indicating the side of the main lesion. Great reliance could also be placed on dilatation and fixity of one pupil as indicating that the major cerebral lesion was on the same side of the body. This sign was particularly valuable when other neurological evidence seemed to indicate that the lesion was on the opposite side. The whole subject of pupillary reactions in head injuries was very complicated, and was worthy of close investigation. Mydriatics and morphia should never be used in cases of head injury.

Mr. Cairns went on to deal with injuries to the geniculo-calcarine pathway, remarking that the occipital lobe was frequently damaged in head injuries. Except in perforating injuries, however, the damage was superficial and tended to be limited to the occipital pole and the outer aspect of the occipital pole, thus sparing the greater part of the visual area. This might, he suggested, explain the fact that homonymous defects of the visual fields were only rarely observed in head injuries in civil practice. Inability to read words and letters and to recognise objects, though visual acuity was good, was observed not infrequently in association with intracranial tumours, and in vascular disease and penetrating injuries of the brain. Injuries of the fibre-tracts and nuclei which controlled movements of the eyes seemed to be rare, at least in cases of head injury which recovered from the immediate effects of the injury.

Finally, the speaker dealt with disturbances of vision in persistent cerebral contusion. Some patients, after a blow on the head, perhaps only of slight degree, suffered from persistent headache and attacks of dizziness, these attacks being brought on or aggravated by exertion. As neurological examination was negative, there was a tendency to regard the condition as functional. He suggested, however, that the basis was an unresolved cerebral contusion. Most of these patients had subjective visual disturbance, with an ache behind the eyes, sometimes with photophobia.

Mr. CHARLES GOULDEN dealt with the subject from the ophthalmological aspect. He began by referring to Mr. Bathe Rawling's Hunterian Lectures of 1904 on Fracture of the Skull, which shed valuable light, he said, on several problems, and laid down principles of diagnosis whereby the probable course of fracture could be predicted if the site of the blow was known. 60 to 70 per cent. of cases of fracture of the base were shown to be due to direct violence applied to the neighbourhood of the base of the skull, whereas 30 to 40 per cent. of basal fractures were due to radiation from fractures of the vault. The path which a fracture of the base might take was largely determined by the various fissures and foramina of the base. Rawling had shown that a fracture involving the optic canal might occur in any fracture of the skull, and such a fracture was more probable when the injury to the head was in the neighbourhood of the orbit. In a certain number the result was partial or total primary optic atrophy, the lesion being in nearly all cases unilateral. After a blow on the head, usually near the orbit—perhaps not sufficiently severe to cause unconsciousness—the eye on the side of the injury was blind. The pupil was dilated and inactive, there was no perception of light, and the ophthalmoscope revealed no pathological signs. After an interval of two to six weeks the appearance of primary optic atrophy was found with normal blood-vessels. In fracture of the middle fossa there might be injury to the optic chiasma, due to laceration by a fragment of bone, crushing or compression, and the optic tracts were exposed to some similar injury. Such injuries would lead to defects in the visual fields; and cases had been reported of bitemporal hemianopia, presumably due to laceration of the chiasma in its inner part. There might be total blindness in one eye and temporal hemianopia in the other.

Mr. Goulden drew attention to the value of the pupillary reactions in cases of injury to the optic nerve in fracture of the skull. Reflex iridoplegia had been observed after injury to the skull. The other nerves liable to injury in fracture of the base were the oculomotor, the trochlear, the trigeminal, the abducens, and the facial. The nerve most commonly involved was the abducens, with consequent paralysis of the external rectus. The oculomotor nerve was only rarely affected. In fractures involving the sphenoidal fissure there might be a complete internal and external ophthalmoplegia, but in that event there was usually an involvement of the other nerves which passed along the cavernous sinus and through the sphenoidal fissure. The fifth nerve was rarely affected in fractures of the base of the skull. The facial was that most involved in these accidents; Boehm found it involved in 22 per cent. of cases of fractured base. The internal carotid artery was most liable to injury at the point where it crossed the line of fracture from one middle fossa to the other.

A number of other papers were read during the Congress, and an exhibition of ophthalmic instruments and other exhibits was held.

MATERNITY AND CHILD WELFARE.

FIFTH ENGLISH-SPEAKING CONFERENCE.

LONDON, JULY 2ND–4TH, 1929.

A CONFERENCE organised on behalf of the National Council for Maternity and Child Welfare by the National Association for the Prevention of Infant Mortality in coöperation with the M. & C.W. Group of the Society of Medical Officers of Health was held last week at Friends House, Euston-road, London, N.W. Brief notice has already been given to the opening session which dealt with the welfare of the child between 1 and 5 years.

Presidential Address.

In his encouraging and inspiring presidential address, unavoidably postponed until the third day of the conference, the Minister of Health, Mr. ARTHUR GREENWOOD, welcomed the overseas visitors and expressed his good wishes for the success of Dame Janet Campbell's forthcoming visit to Australia. He went on to refer to the progress made in the reduction of infant mortality and to the great possibilities of further progress. There were still black spots and we did not get a hundred per cent. value from existing regulations. We must look backward to the mother and forward to the school-child. Maternal mortality was a most obstinate problem and for its defeat a new holy war in a real crusading spirit was needed. Education would gradually overcome reluctance to attend antenatal centres. They must have widespread vision and a long distance and comprehensive programme. It was futile to leave the child alone when a half-finished product and, without being grandmotherly or grandfatherly, they needed to exercise constant watching care from birth to death to ensure the best citizenship. Most children were born normal, and the problem was how to keep them so. He hoped to be able to do something to improve the status of the midwife and to leave his mark on the public health service. He had the highest regard for voluntary workers. There was not enough of such work. Enthusiasm was reborn at every such conference as theirs.

MATERNAL MORBIDITY.

A whole day was devoted to the consideration of various aspects of this subject, the morning session being presided over by Prof. A. Louise McIlroy, D.B.E., and the afternoon by Surgeon J. S. Boggess, representing the U.S.A. Government.

Maternity Nursing.

This discussion brought out unanimity among the speakers and the auditors that every woman should be attended at her confinement by a well-trained midwife and that such midwives should have an improved status and a higher remuneration, so that better educated women may be attracted to the profession and that those who adopt it may be in a position to devote a greater knowledge and more time to each case. It follows that in many or most cases the midwives will have to be subsidised, or the maternity benefit will need to be increased and more carefully allocated; and that the handy woman will have to disappear as a midwifery attendant but may join the ranks of the home helpers.

Several speakers referred to the higher status of midwives in Sweden, where they have been recognised since 1700. In Sweden the maternal mortality is only half what it is in this country, and the Swedish midwives undergo a much more complete training, including a course in pædiatrics.

Dame **JANET CAMPBELL** pointed out that only an adequately trained woman was able to note in the interests of both mother and child the slightest departure from the normal, and that the visiting midwife can do much to avert disaster if she is able to devote more knowledge and time to her cases. The best way, she said, of getting rid of the handy woman is to make the services of a midwife easily obtainable by all patients needing maternity nursing. The problem was mainly an economic one. By encouraging the midwife we could get better nursing and relegate the untrained woman to her proper function as a home help.

Dr. J. S. **FAIRBAIRN** agreed that nursing attendance on confinements should be restricted to certificated midwives and emphasised the points that the experienced midwife of the right type was successful in obtaining a maximum of normal deliveries and normal lactations and in securing surgical cleanliness during the puerperium, and was in a position to make reliable reports to the doctor as to the progress of both mother and baby. Till every mother, Dr. Fairbairn concluded, had a certified midwife to nurse her and the handy woman and all inferiorly trained nurses were wiped out, puerperal morbidity would continue more rife than it should be.

Miss E. **DOUBLEDAY** (College of Nursing), in approaching the subject from the nursing point of view, was in entire agreement with the two previous speakers, and gave in some detail a description of the many functions and duties of a midwife which called for expert knowledge. The medical profession, she said, must insist that maternity nursing be only done by certified midwives. She concluded with a plea for the education of the public as to the need for improved maternity nursing both for those who can and for those who cannot pay.

Other points made in the discussion were—that at 30*s.* a case a midwife cannot earn an adequate income, that hospital extern departments are reluctant to undertake the nursing of abortions, and that there is a real danger to the patient if the midwifery attendants suffer from catarrhal symptoms, especially in times of epidemics.

In replying on the discussion, Miss **DOUBLEDAY** said that the local authority had power to pay for the services of a maternity nurse and she expressed her opinion that extern cases should be nursed by the hospital staff and that the payment of a separate fee for antenatal work would be a retrograde step.—Dame **JANET** agreed that the nursing of miscarriages was neglected. She also stressed the point that the working-class woman cannot pay an adequate fee, and that greater facility for the provision of trained maternity nurses is a more effective method of getting rid of the handy woman than penalisation.

Home Helps.

In addition to doctor and midwife someone is needed to look after the domestic comfort of the household if the mother is to enjoy the physical rest and peace of mind which she requires. Miss F. E. **WRIGHT**, assistant superintendent of health visitors, described the Birmingham scheme for supplying home helps at charges diminishing in proportion to the family income; and at the same time deplored the small use made of this service up to the present. Forty home helps were employed in the city and attended 404 cases during 1928, whilst the number of births was 17,222. The payment made to the home helps was 5*s.* a day (from 8 A.M. to about 6 P.M.) and she is expected to provide her own food.

Dr. S. G. **MOORE** said that Huddersfield provided free home helps and Dr. **FRANK ROBINSON** could not understand why they received so few applications for home helps under their Cambridgeshire scheme.

Mrs. **BLAKE** (Crewkerne) said her authority only contributed towards a home help if a maternity nurse had been engaged.

The Question of Abortion.

In this discussion there was general recognition of the fact that criminal abortion is very largely on the increase in most countries, and that it is a very common cause of fatal puerperal sepsis. There are no statistics available in this country but appalling statistics are available from Germany. As it is agreed that spontaneous abortion does not usually lead to sepsis or a fatal result, and as therapeutic induced labour in skilled hands only exceptionally gives rise to fatalities, it may be inferred that, practically speaking, every case of sepsis or death following abortion is due to criminal abortion.

Dr. **COMYNS BERKELEY**, in opening the discussion, said there had been no improvement in the death-rate from childbirth or puerperal sepsis in the last 20 years. He described the essentials for an improved medical service: better educated doctors and midwives; more hospital beds; antenatal centres linked up with a consulting antenatal centre preferably at a hospital, &c.; and he laid especial stress on the need for educating the public as to the required remedies. Midwifery was the worst paid profession in the world. He pointed out that legitimate induction of labour was not dangerous. Criminal abortion was greatly on the increase and a common cause of sepsis.

Miss **SUSAN MUSSON** (general secretary, National Council for the Unmarried Mother and Her Child) spoke as to the widespread prevalence of the sale of drugs as abortifacients. Her Council could speak from the knowledge of nearly 8000 cases in the past ten years. The death-rate from childbirth among unmarried mothers was twice as high as among married. In their case department they listened to astounding stories of the pills, powders, and potions which had been advised and administered. Their most dangerous enemy was the retail shop which sold "pills for ladies," "female pills," or "pills to remove irregularities." Trade by correspondence was very common, though the Advertising Association had recently persuaded the press to refuse such advertisements. Unfortunately, the firms which supplied abortifacients, or supposed abortifacients, also dealt largely in birth control accessories, and abortifacient drugs were supplied through advertisements which purported to deal *only* with birth control. There was a loophole in the law as to the sale of lead preparations, in that lead plaster made by machinery was excluded and she had been informed by a leading gynæcologist that a woman could buy for a penny enough diachylon plaster to poison herself, cause abortion, and leave her a mental and physical wreck. The Home Office should be pressed to deal with this matter. Miss Musson's conclusion was that public opinion must be educated to deal less hardly with the unmarried mother in order that she may shun these so-called remedies, which endanger the life of herself and her child.

Mr. F. E. Scrase, F.R.C.S. (M.O.H., Hampstead), described the scheme for a panel of consultant gynæcologists and obstetricians which was working satisfactorily in his borough.

Dr. Dorothy R. Mendenhall (U.S. Children's Bureau) read a paper on maternal mortality in the U.S.A., and gave statistics as to the variations of the maternal death-rate between one State and another and among the white and coloured populations. The latter were largely attended by untrained midwives. A study by the Bureau extending over a two-year period, not quite completed, indicated that deaths following abortion contributed largely to maternal mortality and particularly that from sepsis. In the discussion it was pointed out that the recent increase of criminal abortion was very largely among married women (one speaker referred to a wife who had performed abortion on herself seven times), and the advocates of birth control claimed this as a cogent reason for giving sound advice as to contraceptive methods.

Other points made were: that women taking drugs will not attend antenatal centres; that there is no hospital treatment for abortions, and consequently no adequate education of medical students in the treatment of abortion.

Special V.D. Clinics.

A whole session was allotted to a discussion on the holding of special venereal disease clinics for women and children in connexion with maternity and child welfare departments. The main points emerging were: the need for a better linking up of all the medical services for the discovery of venereal disease with a view to securing special treatment in well-equipped premises with no label attached to them, and particularly the devising of methods which make it easy for the pregnant woman to secure early treatment; and also the need for combating the greatly exaggerated view held by both the medical profession and the public as to the risk of contagion.

In his introductory remarks Mr. E. B. Turner, F.R.C.S. (Chairman of the Executive Committee, British Social Hygiene Council), voiced the anxiety of his Council to see all maternity and child welfare centres equipped with facilities and means for diagnosis, and the establishment of special clinics at unlabelled premises for the treatment of married women.

Dr. David Lees (V.D. Medical Officer, Edinburgh) said that 60 per cent. of these diseases were not acquired through illicit sexual intercourse. The amount of gonorrhœa under treatment had increased but we were not yet treating anything like all of it. Gynæcological hospitals, children's hospitals, maternity hospitals, and maternity and child welfare centres were not used as they might be in their schemes. The last named should at least have the means of diagnosis. The labelling of discharges in pregnancy as venereal should be avoided. A centralised control of their schemes was very important. Health visitors were not at present educated for following up V.D. cases. With ordinary care there was no danger from contagion or cross-infection in hospitals. In new general hospitals there should be first-class equipment and service for dealing with venereal diseases. There should be no labelling and the same waiting-room should be used for different purposes at different hours.

Dr. Violet Russell (V.D. Medical Officer, Guy's Hospital) favoured treatment for pregnant women at maternity centres. There should be proper facilities for diagnosis and a consultant available at all centres. Special difficulties arose from the attempt to transfer pregnant women from the centres to the V.D. centres for treatment, and, in order to secure the desired result, everything must be made easy and pleasant for the pregnant woman. Children with congenital disease and their mothers, when not pregnant, could be treated at the V.D. clinics. She had met with cases of gonorrhœal vulvitis in girls spread by unhygienic w.c. seats, and advocated the use of seats such as those used on the Continent. As the result of five years' experience at the antenatal clinic, they had found 5 per cent. with a positive Wassermann reaction. Diagnosis was often difficult clinically and the patient was frequently unaware of her complaint. The medical officer of the antenatal clinic should not wholly let his patient go but should call in the V.D. officer to carry out the special treatment. Lock hospitals should be abolished. Their great aim should be to secure the antenatal examination of every pregnant woman and the early treatment of every syphilitic so found.

Dr. Norah I. Wattie (Assistant V.D. Medical Officer, Glasgow) thought that antenatal supervision in Scotland was now extended to about 50 per cent. of pregnant women. She alluded to the difficulties in the diagnosis of gonorrhœa and advocated several examinations. Treatment was provided in Glasgow at the centres but cases requiring daily treatment received such at the V.D. clinic, while still attending once a week at the centre. This compromise worked satisfactorily.

Dr. Naylor Barlow (M.O.H., Wallasey) complained that the Ministry had recently refused to give consent to the establishment of a first-class composite clinic, including V.D. in Wallasey.

Dr. D. Brewer (M.O.H., Swindon) said that suspects should not be sent to the V.D. clinics. He would like to see the special treatment carried out by special officers at a general clinic as proposed at Wallasey.

Miss Musson advocated the treatment of expectant mothers at maternity hospitals.

Dr. P. S. Blaker (Dudley) stated that they had appointed a new V.D. officer to do antenatal and other work with facilities for immediate diagnosis at the centres, thus linking up the V.D. with the M. & C.W. work.

In reply, Dr. Lees expressed his opinion that gonorrhœa was not a cause of puerperal septicæmia but rather of a sapræmia arising about the tenth to the fourteenth day. Antenatal work diminished the risk of septicæmia. Any child born with a syphilitic rash in a maternity hospital was a reflection on our schemes and meant failure to secure antenatal supervision and early treatment. He spoke approvingly of the great increase of suspects at their clinics in Edinburgh. Linking up well-equipped premises for the work, and a juster appreciation of the real risk of contagion were both very necessary. As these diseases were so frequently not acquired "venereally," he preferred to call a spade a spade and to talk about gonorrhœa and syphilis rather than venereal disease.

Work of Guy's Hospital.—The annual report of this great institution shows that in 1928 11,000 in-patients and 120,000 out-patients were treated at a cost of £180,000; out-patients made 517,000 attendances. The income from endowments was £60,567, but the annual subscriptions amounted only to £6,000. The downward movement of the rate of mortality which for three years had remained stationary at 6·6 per cent., has been resumed, and last year was 6·2 per cent. There has been a remarkable growth of confidence in the venereal diseases clinic. In 1924, its first year as a whole time clinic, the attendances numbered 21,700; in 1928 they were 61,148. The percentage of cases discharged as cured shows a marked upward curve. A new departure is the allotting of four beds to cases requiring extensive or special types of dental treatment. In the State examinations Guy's nurses were notably successful, only four out of 78 failing in the preliminary, and two out of 64 in the final. At the close of the year the total number of available beds was 640.

Reviews and Notices of Books.

A TEXT-BOOK OF PULMONARY TUBERCULOSIS FOR STUDENTS.

By R. C. WINGFIELD, M.B. Oxf., F.R.C.P. Lond., Medical Superintendent. Brompton Hospital Sanatorium, Frimley. London: Constable and Co., Ltd. 1929. Pp. 401. 31*s.* 6*d.*

THIS book is clearly written and full of information which will be appreciated not only by the student but also by tuberculosis officers and others interested in consumption. The first few chapters deal with epidemiology and the effect of the tubercle bacillus on the tissues, and here we are in the realm of debate, but the author's arguments are well expressed, and his summing up of the experimental work and views of different authors is lucid and convincing. He emphasises the fact that tuberculosis in the adult is practically confined to a chronic disease of the lungs and cannot be compared to tuberculosis in the infant, where the manifestations of the infection are so different that they produce quite another type of disease. The decline in mortality is ascribed to urbanisation, which, though leading to a preliminary rise in the death-rate, is followed by a fall as the succeeding selected generation, immunised by the infantile infection, reaches adult age. The adult is relatively immune, but if an old lesion (not of necessity in the lung) becomes active or reinfection takes place at a time when immunity happens to be at a low ebb the bacilli may multiply and be carried to the lungs in sufficient numbers to cause phthisis.

There is a very full account of methods of physical examination, but the reader is warned that physical signs no longer hold the " pride of place in the equipment of the chest specialist " as in days gone by. The thorax is by no means built to pattern, and, therefore, even in health, sounds heard on auscultation or percussion will vary, and what is normal in one may be abnormal in another. The importance of a careful and thorough physical examination is admitted, but in most cases symptoms and other means of examination point to a true diagnosis before the appearance of physical signs, and the old habit of giving a clean bill of health because no signs are detected is fortunately passing away. The author rightly emphasises the fact that it is not enough to say " this patient is infected with tubercle bacilli," but one must also go on to say whether the symptoms are or are not due to that infection. In Chapter IX., which deals with classification and assessment, it is clearly explained that although pulmonary tuberculosis is one disease, yet it is a disease of many phases, each requiring different treatment.

The last eight chapters are devoted to treatment, and it is most refreshing to find so much space given to such an important subject. The reader is warned to shun the extremist, and the author himself keeps an open mind. For example, he does not regard tuberculin as a really valuable method of treatment, yet he devotes a whole chapter to a fair discussion of its possibilities and limitations. The description of sanatorium treatment is of special interest for the purpose of the treatment is made clear, and one can therefore understand why certain patients are unsuitable and others obtain great benefit. The chief criticism of the sanatorium system is that it fails with advanced cases, but, after all, its main object is to prevent mild cases from becoming advanced. Many a life is thrown away by waiting for the patient to pass from the early and curable into the later and incurable stage before advising sanatorium treatment. We agree with the author that the physician who bewails the results of sanatorium treatment among his patients is oftentimes but bewailing his own inefficiency. The technique of the simpler laboratory methods are described in a brief appendix, and the book concludes with a useful index.

A text-book on tuberculosis was wanted. This one can be thoroughly recommended to all interested in tuberculosis, not only as a text-book but also as a work of reference.

HANDBOOK OF CLINICAL CHEMICAL PATHOLOGY.

By FRANK SCOTT FOWWEATHER, M.D., M.Sc., D.P.H., F.I.C., Lecturer in Chemical Pathology, University of Leeds. With a foreword by Sir BERKELEY MOYNIHAN. London: J. and A. Churchill. 1929. Pp. 216. 8*s.* 6*d.*

IT is obvious that the study, by means of chemical analyses, of the fluctuations and alterations of the body's functions has thrown considerable light on the mechanism of disease, and in this field the subject of chemical pathology has surely still more to give to us. Its chief interest to the medical profession appears to be on a somewhat lower plane, for the demand for new and practical methods of diagnosis by means of what are usually described as " laboratory tests " is insatiable. In an age when most of us are afraid of not being up to date these tests are much in vogue; and the author of this book, realising the inherent dangers of such a situation, has set out to describe how, when, and why they should be carried out. It is not a laboratory manual, and all details of the actual methods of analyses have therefore been avoided. The investigation of renal function, liver function, gastric function, and so on are dealt with on conventional lines in a simple manner which should be useful to the student. Apart from the description and discussion of diagnostic tests there are other chapters devoted to some of the recent advances which have been made in medicine. In these are described the vitamins and deficiency diseases, basal metabolism, anoxæmia, acid-base balance, and the toxæmias of pregnancy.

There is no information in the book which is not already available elsewhere, for the most part in the series on Recent Advances issued by the same publishers. But Dr. Fowweather presents it clearly and concisely and has produced a useful guide to the subject. The chief disappointment of the book is that the reader is left in considerable doubt as to the value of some of the tests. We exclude from this criticism the chapters on the investigation of pancreatic and intestinal conditions where definite pronouncements are made on the uselessness of many tests and on the value of others. The experience of the Leeds school, which has such a high reputation for surgery, on the value of chemical tests for the diagnosis of cancer and ulcer of the stomach, would have been interesting. Tests for occult blood in the fæces are highly esteemed in some places and neglected elsewhere. For these very reasons, perhaps, the author has been content to describe some of the tests and to leave their assessment an open question.

THE TROUBLED CONSCIENCE AND THE INSANE MIND.

By CHARLES BLONDEL, Professor of Psychology in the University of Strasbourg. With an introduction by F. G. CROOKSHANK, M.D., F.R.C.P. London: Kegan Paul, Trench, Trübner and Co., Ltd. Pp. 91. 2*s.* 6*d.*

THIS little volume is one of the Psyche Miniature Series, and will prove of very genuine interest to psychiatrists, and to the general reader with a taste for philosophical study. It is not quite clear who is responsible for the admirable translation from French into English, but Dr. Crookshank provides an introduction in which he gives a résumé of the psychological conceptions behind Prof. Blondel's essay. The translation is so good that the reader would forget that the essay was originally written in French but for the constant use of the term " delirium," not only in the usual English sense of the word, but also as a synonym for " psychosis."

The book is an attempt to explain the irrational and dissociated behaviour and language of the insane.

The author points out that the speech of insane persons ceases to be language, since it fails to make their meaning clear, either to others or to themselves. This fact the writer attributes to a fundamental difference between the experience of the insane as compared with the sane. Dr. Blondel insists that full consciousness in the normal must consist of two parts, and that for normal consciousness a certain separation takes place, similar to the pouring off of one liquid from another. Healthy minds select only those experiences which are identified with collective experience and find ready linguistic expression. Those sensations and feelings attributed to the viscera and the activities of the vegetative nervous system (cenesthesia) remain on the fringe of consciousness, and have no place in language. Dr. Blondel supposes that the insane mind, with its feelings of depersonalisation and obvious disorder of expression, is due to the invasion of normal consciousness by cenesthesia, with consequent failure on the part of the patient to find adequate verbal expression for his experience.

These brief sentences give but a meagre idea of the purpose of the essay in which the reader will find material help in clarifying his ideas of the relationships between body and mind. There is but little reference to Freudian conceptions; in a sense the book may be regarded as an attempt to place the conception of the unconscious on an organic basis. The influence of cenesthesia in the normal mind is perhaps underrated by Dr. Blondel. It is obvious that the work owes much to the writings of Derkheim and Bergson.

The Excitability of Muscle.

Handbuch der Biologischen Arbeitsmethoden—Methoden zum Studium der Funktionen der Einzelnen Organe des Tierischen Organismus. Abt. V. Teil 5A, Heft 5. Berlin: Urban and Schwarzenberg. 1929.

THIS section of Abderhalden's "Handbuch" contains a detailed account of Lapicque's methods of measuring excitability, translated from the French of Henri Laugier. Theoretical considerations are discussed only in so far as they are needed to make the applications of the methods intelligible. The section includes also an essay on the measurement of tone, and one on the methods used in the investigations on plain muscle. Both these give adequate descriptions of current practice, but the bibliographies reveal a degree of "insularity" which is commoner perhaps in continental than in English writers. While this engenders a doubt as to the comprehensiveness of the authors' erudition, it hardly reduces the interest for readers in this country.

Cancer.

A Practical Résumé of the Subject for General Practitioners. By G. JEANNENEY, Professor in the Faculty of Medicine, Surgeon to the Hospitals of Bordeaux. Translated by JOHN GIBSON, *M.C.*, M.A., M.D.; and JOHN H. WATSON, M.B., B.S., F.R.C.S. London: H. K. Lewis and Co., Ltd. 1929. With 33 illustrations. Pp. 186. 7*s*. 6*d*.

THE object of this little book, as stated in the foreword, is to recall to the practitioner as shortly as possible the elements of the diagnosis of cancer at its onset in order to ensure early treatment. Consideration is therefore given only to the clinical aspects of the disease. The author says that he has endeavoured "to emphasise facts which will be true in ten years' time—except in the case of treatment—for clinical manifestations do not change." He proceeds, however, to make a statement which is not true to-day and will not be true ten years hence—namely, that there are cancer houses and cancer villages. The discussion of the pathology of the condition is inadequate. The book consists mainly of a brief account of the clinical symptoms of the disease in the different organs for the purpose of providing help in diagnosis. This is followed by a short account of treatment—surgical and radiological. In so far as the carrying out of these forms of treatment is not within the province of the practitioner, this section might well have been curtailed to provide more space for one of the most difficult tasks which a practitioner has to face—the medical treatment of cancer in its final stages. This subject is dismissed in two pages. The book does not contain any information which might not be found in any good text-book on surgery. The translation is well done.

Kraemer's Scientific and Applied Pharmacognosy.

Third edition. By an Editorial Committee consisting of Editor-in-Chief, EDWIN L. NEWCOMB, P.D., Ph.M., Phar.D., Secretary National Wholesale Druggists' Association; and Co-Editors, LEASURE K. DARBAKER, Phar.D., Professor of Histological Pharmacognosy, University of Pittsburgh; EARL B. FISCHER, B.S., Professor of Pharmaceutical Botany and Pharmacognosy, University of Minnesota; EDMUND N. GATHERCOAL, Ph.G., Professor of Pharmacognosy, University of Illinois. London: Chapman and Hall, Ltd. Pp. 893. 37*s*. 6*d*.

IF to the medical man of to-day pharmacognosy or the recognition of drugs and the study of crude materials is a subject of little interest, it is because the competition associated with the commercial development of pharmacy has led to an almost embarrassing supply of purified and standardised products from which he can choose the one most suitable for his purpose. The intensive study of crude drugs now lies more in the domain of applied botany and chemistry than of medicine, but the doctor should be able to recognise some of the more commonly employed preparations and to know something of their properties. He will find these, as well as rare preparations, well described in this book, written by the late Henry Kraemer in 1910, which reached a second edition in 1920, and has now, after the death of the author, been revised for a third edition by an editorial committee, four of the best known pharmacognoscists in the United States. The general plan of the text has been retained, the statements relating to morphology have been checked, and information concerning the constituents of drugs has been critically reviewed and revised in the light of recent research. The chapters on commercial starches and on bacterial remedies have been entirely rewritten, and numerous minor alterations have been made with a view to increasing the accuracy and value of the work. A new key for the analysis of powdered drugs by means of the microscope has been introduced. The book, we anticipate, will continue to be of great assistance as a text-book for students of pharmacy, and as a work of reference for botanists, chemists, food and drug analysts, and pharmacologists. The lay reader should not accept as strictly accurate some of the brief statements regarding the general action and therapeutic uses of drugs, which the editorial board has introduced into this edition.

Popular Books on Food and Health.

Food. By ROBERT MCCARRISON, C.I.E., M.D., D.Sc., LL.D., F.R.C.P., Director of Nutritional Research, Pasteur Institute, Coonoor, S. India. Madras: Macmillan and Co., Ltd. 1928. Pp. 115. 1*s*.

Good Health. By IAN S. THOMSON, M.A., M.D., D.P.H. With a foreword by Sir ARTHUR KEITH, M.D., LL.D., F.R.S. London: Longmans, Green and Co. 1929. Pp. 122. 3*s*. 6*d*.

THE number of popular books on health is very large, but the quality of most of them is poor. These two volumes, however, show how much sound information can be given in simple language by an expert at exposition. Col. McCarrison's book is intended as a primer for use in schools, colleges, welfare centres, boy scout and girl guide organisations in India, where nutrition is one of the most pressing problems of the day. If the young people can be taught what to eat and why to eat it, a great step will have been taken towards improving the health of the nation. The author makes his instruction interesting by supplying concrete details. He builds his description of the component parts of food round a "food star" and takes the child by easy stages from air, sunlight, and water right through to vitamin D. He discusses the foodstuffs in common use and points out the faults of Indian diets and of Anglo-Indian and European diets in India and shows how these could all be rectified. The effect of diet on the teeth and the physiology of the gastro-intestinal tract are described, also the amount and balance of foodstuffs required in a perfect diet. There are just over a hundred pages in this little book, but the instruction is given in concentrated form without padding, and it can be recommended as a model of its kind.

Dr. Thomson's book is extremely well written. The author is the son of Prof. J. Arthur Thomson whose popular writings have a wide and appreciative public and has evidently inherited the rare gift of presenting a difficult subject in a clear way without becoming sensational or sentimental. Moreover, he is free from fads and as far as possible presents facts in such a way that the reader may make his own judgments. There are 20 chapters in his book and none of them is dull. He begins with the infant, with a throw-back to bring in antenatal influences, and then deals with such subjects as digestion, ductless glands, mental diseases in separate sections, arranged on no very definite plan. Dr. Thomson has included some useful chapters on subjects not generally discussed in books of this type, such as State medicine and patent medicines. The book is essentially a pleasant collection of essays which medical men as well as laymen will read with pleasure.

THE ORGANISATION OF AN OPERATING THEATRE.

Organisation und Ordnungsgemässer Betrieb des Operationssaals. Von Prof. Dr. MAX KAPPIS, Hanover. Leipzig: Georg Thieme. Pp. 119. M.4.8.

THIS little volume gives an accurate and detailed description of all the technical requirements of the operating theatre, and should be invaluable to those who have to organise this highly specialised branch of technical surgery. Not only is the equipment of a theatre fully described, but most precise details are given as to the best methods for the sterilising of all materials, the preparation of catgut, and of every solution that the surgeon can possibly require. No such elaborate handbook has been published in English, and we hope that Prof. Kappis will earn the gratitude of English surgeons by arranging for its translation.

TROPICAL NURSING.

A Handbook for Nurses and Others going Abroad. By A. L. GREGG, M.D., M.Ch., D.T.M. & H. Lond. With a foreword by the Hon. Sir ARTHUR STANLEY. London: Cassell and Co., Ltd. 1929. Pp. 199. 6s.

THIS little book does pioneer work in giving to the nurse trained at home and going abroad for the first time a guide which should enable her to keep her health and to cope with strange and new emergencies till medical help arrives. It deals first with personal hygiene, and next, in a section which fills most of its pages, with a series of diseases which are important in different parts of the tropics. For example, in beri-beri great emphasis is laid on the need of extreme care to avoid all risk of blame for a sudden heart failure; any relaxation of the vigilance advised in the book should be allowed only by doctor's orders. Blackwater, cholera, the dysenteries, malaria, sprue, yellow fever, and worm infections, to name a few only, are well considered. But the anthelmintic dosage for intestinal infections is perhaps higher than seems wise in a book destined for nurses, the author holding 1 drachm as the equivalent of 3 c.cm. of carbon tetrachloride, though a table of weights and measures at the end of the book supplies the proper ratio. This valuable section is followed by another on the techniques used for blood examination and transfusion, for bowel lavage and the test-meal, and for intramuscular and intravenous injections. There is also a note on the care of the eyes and a glossary of medical terms which will be particularly valuable for those laymen who, the author reasonably hopes, will find useful material in its pages. The nurse trained in the tropics, as so many now are, will also glean from it much to help and interest her.

DENTAL ANATOMY.

Classroom and Laboratory Quiz Compend. By W. C. STILLSON, D.D.S., Associate Professor of Dental Anatomy, Western Reserve University, Dental School. London and Philadelphia: W. B. Saunders Company, Ltd. 1929. Pp. 280. 10s.

IN America the coaching class is picturesquely called the quiz class. But while the method of question and answer is well adapted to put the student on his mettle and enable the teacher to assess his knowledge, we are doubtful whether the method when applied to revision or cram books is satisfactory even from the standpoint of helping the student to pass his examination. This book consists of a large number of brief questions with brief answers, many of them so trivial and obvious that even the student ridden with the obsession that every examiner is out to trap him, could not but know the correct reply. Dental anatomy if properly taught can be quite an interesting subject, but no one reading through this dreary compilation could possibly believe this.

JOURNALS.

THE INDIAN JOURNAL OF MEDICAL RESEARCH for April, 1929, Vol. XV., No. 4, contains some 29 contributions.—N. H. Fairley continues his studies on sprue with F. Jasudasan, and shows that the complement reaction in sprue with *Monilia psilosis* vaccine is of no value.—B. N. Chatterjee and E. W. H. Cruickshank have studied the comparative histology of the spleen in various vertebrates and the effect of iron on the hæmogenic organs.—L. E. Napier has two comparative papers on Urea Stibamine and Stibamine Glucoside.—R. N. Chopra and S. G. Choudhury write on the causation of the formol-gel reaction in kala-azar and physical properties of different blood sera.—C. G. Pandit, S. R. Pandit, and Seetharama Iyer on the Adhesion Phenomenon in Filariasis and on a new species of Filaria Worm in Birds.—T. C. Boyd and A. C. Roy describe some Biochemical Aspects of Chyluria.—A. D. Stewart and S. C. Ghosal have investigated the germicidal action of the activated sludge process.—S. Khan and M. N. Agarwal have studied the Duration of Life in the Vibrios in the Ganges and Jumna River Water.—S. D. S. Greval writes on the Kahn, Microkahn, and Wassermann Reactions in a study of 2066 cases.—V. T. Korke believes he has discovered *Filaria malayi* in India.—J. Cunningham describes a new Technique for Handling Infected Monkeys.—Clive Newcomb has a paper on the Composition of Vesical Calculi in India.—P. J. Barraud continues his revision of the Culicine Mosquitoes of India.—R. B. Lloyd, L. E. Napier, and S. N. Paul believe that the serological observations are useful in the control of the treatment of kala-azar.—H. W. Mulligan has studied the reticulo-endothelial system in malaria.—R. Row has made observations on malarial parasites grown aerobically in simple cultures with special reference to the evolution and degeneration of crescents.—T. N. S. Raghavachari and S. Y. Ganepati describe observations on the water of the Red Hills Lake at Madras.

THE LANCET.

LONDON: SATURDAY, JULY 13, 1929.

THE ORTHOPÆDIC CONGRESS.

A RECENT feature in our science has been the velopment of orthopædic surgery, arising out of e need for increased knowledge and perfection of hnique felt when the war brought into all the spitals of Europe an influx of mutilated men. very nation then felt alike the responsibility curred, and the Congress held last week in London hen the Orthopædic Associations of America and his country sat in joint session, has demonstrated he many directions in which orthopædics have dvanced and demonstrated also, alas! how much emains to be done if many crippling and painful onditions are to be removed or mitigated.

The programme of the Congress had this interesting ide—it revealed a pre-occupation with common esions which should encourage the family doctor. The ubjects discussed were of wide practical interest to he profession as a whole, and nearly every speaker howed that without the coöperation of the general practitioner the efforts to improve the end-results of treatment would be fruitless. To secure bony union in intracapsular fractures of the neck of the femur; to diagnose at the earliest possible moment congenital dislocation of the hip, which becomes such a serious deformity when neglected; to shorten and simplify the course of chronic sepsis in bones; to deal with those very common and tedious cases of low back pain—all these are problems which confront the practitioner daily, and their solution depends largely on the rules which the specialist is able to formulate for his guidance. But the orthopædic surgeons are powerless to test new theories or to assess the value of practical measures based on mechanical principles without enlisting the practitioners' interest. Nothing is more likely to ensure such coöperation than the conviction that not only the fractured femur and the victim of anterior poliomyelitis, but the man with an intractable pain in the lower part of his back is the subject of scientific consideration. The communications submitted were of high merit. Among the most illuminating was the address on the basic principles involved in the treatment of the common spinal conditions as well as in the functions of the viscera, in which Dr. J. E. GOLDTHWAIT demonstrated the anatomical, physiological, and pathological data on which is based the whole system of posture training for which his name is famous. The most entertaining was the film, built up on the lines made familiar by the antics of "Felix the Cat," in which Dr. WILLIS CAMPBELL demonstrated his operation for foot-drop, leaving a most vivid impression of the essential stages of the operation. The most depressing were the group of communications dealing with fracture of the neck of the femur, since most surgeons using different methods gave statistics showing non-union in 30 per cent. of cases, some confessing to a rate as high as 45 per cent. Dr. ROYAL WHITMAN, whose claims to a much higher record of success are well substantiated, admitted that his patients are specially selected. The treatment of open septic wounds after cleansing without suture by a light dressing of gauze soaked in paraffin, according to the method of Dr. WINNETT ORR, is likely to be tried by some at least of those who were obviously impressed by the results obtained. If the same measure of success is achieved in other hands this conference will be remembered for the initiation of a change of great importance in surgical methods.

What may be called, in a wide grouping, orthopædic cases, while alike in their main results, are so widely separated in their various origins that the family doctor, the general surgeon, and the specialist have in a great majority of instances their combined parts to play. Not only is there no line of demarcation between general and orthopædic surgery, but any of the procedures adopted may depend for their correctness and suitability of treatment upon the knowledge and discrimination of the family practitioner as displayed in early diagnosis and wise preventive care. Orthopædic surgery must be based on general surgery, and must recognise and practise the principles of treatment covering the widest field of surgery; thinking in terms of function mainly must not limit the general view. And this was the general message delivered at the sessions of the Orthopædic Congress.

PREVENTABLE BLINDNESS.

AT the present time it is impossible to say with any exactitude what proportion of blindness is due to causes which may fairly be called preventable, but we can point to certain forms of blindness which would have been prevented if known precautions had been taken. In a recent Richard Middlemore lecture,[1] Mr. W. H. FULFORD EALES puts first and foremost cases due to ophthalmia neonatorum. Statistics show that rather more than 5 per cent. of the totally blind owe their blindness to this cause. Among children the proportion is, of course, far higher, as none of the causes of blindness that appear first in adult life affects them. The problem of prevention is threefold. A great majority of the severe cases of ophthalmia neonatorum have their origin in gonorrhœa and infection of the mother with the gonococcus is preventable. Secondly, the responsibility lies with the doctor or midwife, for it has been abundantly proved that when effective precautions are taken at the birth of the infant the eyes are not infected. Thirdly, the public authority should provide facilities for these necessary precautions, and ensure that they are within the reach of all women at the time of their confinement. The next cause of preventable blindness discussed by Mr. EALES is phlyctenular disease. The incidence of what is technically termed blindness from this cause is, it is true, trifling. On the other hand, the number of those who suffer throughout their lives from seriously impaired vision resulting from phlyctenular keratitis is by no means inconsiderable. Since this disease hardly ever reaches a very serious stage except among the poorer classes, and is undoubtedly connected with bad feeding, absence of sunlight, and overcrowding, it may be said that the main responsibility for this disease lies in the social conditions of our country, and especially of our large towns. Yet it would be a mistake to attribute the whole responsibility to social conditions. It has often been remarked that the Jews, even in the poorest quarters of London, are remarkably free from phlyctenular disease. There may be some racial immunity, but the probable reason is the more nutritious diet, especially in regard to fatty foods, usually enjoyed by Jewish children as compared with other children of the hospital class. The third in order of Mr. Eales's causes of preventable blindness —also mainly affecting children—is interstitial keratitis, a disease due to congenital syphilis. Here, too, the primary responsibility belongs to the parent from whom the disease is transmitted, but the State also has assumed partial responsibility, and by means of its venereal clinics can do, and is doing, much to lessen the incidence of the disease. Mr. Eales quotes Mr. Lindsay Rea to show that the actual treatment of the infected children themselves by antisyphilitic injections can do far more to induce a cure than is sometimes assumed, so that here some of the responsibility lies with the ophthalmic surgeon. Since interstitial keratitis is only one of several syphilitic conditions which cause blindness, whether in children or adults, it would perhaps be better to enumerate syphilis itself as one of the main causes of preventable blindness. The remaining three of Mr. Eales's classes are of traumatic origin, whether it be the blindness directly due to injury, as in perforating wounds of the eyeball, sympathetic ophthalmia, or serpiginous ulcer of the cornea. A considerable proportion of industrial injuries to the eye could no doubt be prevented if workmen at trades dangerous in this respect could be induced to wear efficient goggles. How difficult it is to get this carried out was shown by Mr. Bernard Cridland in a paper[2] read at the recent Congress of the Ophthalmological Society. Of the cases attending hospital for treatment of minor eye injuries, in 70 per cent. he found that no protection had been provided; in 19 per cent. protection was supplied, but not used; and in 11 per cent. protection, although used, was ineffective. Sympathetic ophthalmia is now extremely rare, but it must always be prominent in the mind of the ophthalmic surgeon to whom the main responsibility belongs of diagnosing the condition, with or without the aid of the slit lamp, and making the momentous decision as to when it is safe to allow a patient to retain an injured eye possessing sight and when it is necessary to recommend excision. Serpiginous ulcers also result from injuries to the cornea, often so slight as to be deemed trivial by the patient. The danger lies in the infection of a simple abrasion by the pneumococcus which is apt to be present in the discharge from an infected lacrymal sac. Here the chief necessity is timely and correct treatment, for this form of ulcer, inefficiently treated, may quickly render the whole cornea opaque. At present we are not able to look upon glaucoma and senile cataract as preventable, though blindness from these causes may to a great extent be prevented by early diagnosis and treatment in the one case and timely operation in the other. There remain congenital defects and familiar diseases such as retinitis pigmentosa, and blindness due to septic infection causing cyclitis. The last-named might also be classed as preventable.

SANOCRYSIN.

So many cures for pulmonary tuberculosis have been advocated, have had their day and have ceased to cure, that scepticism about the value of any new remedy and pessimism about the possibility of the discovery of any effective means for treating the disease have become all too prevalent. Tuberculosis may itself be a dying disease, but it still remains one of the commonest and in its results one of the most tragic of all diseases. If our efforts to save the consumptive are often doomed to failure we can still do something to alleviate suffering and to prolong life. It is now universally recognised that, when the disease is unilateral, treatment by artificial pneumothorax should always be considered and usually undertaken. If an effective collapse of the diseased lung can be secured, hope of a complete recovery may be entertained. Unfortunately adhesions prevent complete deflation in the majority of the cases of unilateral disease. Further, bilateral disease is frequently present when the consumptive first presents himself for treatment. Despite the failures of the past we cannot lightly dismiss any new form of treatment which is applicable to cases of bilateral disease and which may therefore be employed when collapse therapy is impossible. The claim for consideration is also strengthened if such treatment by diminishing disease in one lung may enable us to apply artificial pneumothorax to the other. Both these merits have been claimed for the thiosulphate of gold and sodium introduced by Mollgaard under the name of sanocrysin.

Sanocrysin has now had an extensive trial at home and abroad. Its advocates have in the main been cautious in their claims for its efficacy, but there is a consensus of opinion that its action is often beneficial and sometimes strikingly successful. It should also be noted that its chief successes have been obtained in cases of active disease of the so-called exudative type. And these are the forms which, if bilateral, are least influenced by any other form of therapy. Sanocrysin thus differs from tuberculin, a remedy advocated principally in the treatment of the chronic types of disease in which the natural defences of the body often suffice to keep the enemy at bay, whatever form of treatment is applied. Léon Bernard and Charles Mayer,[1] in a recently published article, give an account of their experience in the treatment of 142 cases of acute febrile disease. They claim favourable results in 43 per cent. of the cases as shown by defervescence, gain in weight, improvement in general condition, and some diminution in physical signs. The clinical improvement was correlated with a change in the radiographic appearances, in some cases denser shadows proving the development of a beneficial sclerosis. In others there was noted a lessening of the extent of the diseased areas or even a diminution in the size of cavities. The improvement noted in patients treated with sanocrysin was far greater than that observed in comparable cases not so treated. In the latter spontaneous arrest of acute symptoms was obtained in less than 5 per cent. of the cases treated in the Laënnec Hospital, in contrast with the figure of 43 per cent. for the sanocrysin series. In many instances subsequent relapses occurred, and though permanent benefit was obtained in others, no claim is made for a definite cure.

Used in conjunction with collapse therapy sanocrysin has something more to its credit. When there is bilateral disease sanocrysin may, in the words of

[1] Presse Médicale, May 29th, 1929, p. 705.

FREDERICK HEAF,[2] just "turn the balance from a bad to a favourable result." Thus L. S. T. BURRELL[3] was able to report improvement in five out of six cases of acute disease of this type, tubercle bacilli being abolished from the sputum in four cases. The experience of many other workers has been similar to that of those quoted. The selection of cases suitable for sanocrysin calls for nice discrimination, and the drug must perhaps be regarded as unsuitable for use in general practice. Apart from the minor difficulties inseparable from intravenous therapy, toxic symptoms may arise as the result of metallic poisoning and close observation of patients under treatment is essential. In the past severe dermatitis, nephritis, and gastro-intestinal inflammation have been caused by too frequent administration or too large a dose. Wider experience has diminished the number of accidents of this kind, and with correct dosage complications of any kind are rare.

◆

THE BRITISH EMPIRE CANCER CAMPAIGN.

THE sixth annual report of the British Empire Cancer Campaign[4] contains an account of the work being done in various institutions subsidised by the central organisation, and also records the achievements of committees in the provinces and in the overseas dominions affiliated to the campaign. Moreover, individuals in receipt of grants are given the opportunity of detailing the efforts made during the year, whether or not these have yet been recorded in scientific journals. An editorial survey (pp. 9 to 18) of the work in progress is illuminating, and would be even more useful another year if it included page references to indicate where the work is more fully described, especially since the place where one looks for an index of subjects and names has been allocated to a list of subscribers to the Fund.

The range of activities is wide, for all possible avenues of approach to this most baffling medical problem are being explored under the auspices of the Campaign. *In some institutions the field of inquiry* is deliberately limited, the whole of the grant available from the Campaign funds being concentrated on one branch of research. For example, at St. Bartholomew's Hospital, the Marie Curie Hospital, and the Westminster Hospital scientific and statistical studies of radium therapy are being subsidised, at St. Mark's Hospital precancerous conditions in the rectum. At other places, for example the Middlesex Hospital, the attack is more general, three departments being drawn into the battle. In the pathological department attention has been devoted to tissue culture; the virus theory of cancer; the artificial production of tumours; resistance to tumour growth, and the problems of immunity. In the biochemical department methods of sero-diagnosis of malignant disease have been tested (with negative results); the examination of therapeutic substances has been undertaken; and the metabolism of tumour cells has been studied, especially the abnormal carbohydrate metabolism which is a property of malignant tissues. In the radiological department the three main investigations have been the differential action of X and gamma rays, the limiting intensities of radiation influencing tumour growths, and the general physiological reactions caused by penetrating radiation.

At the Cancer Hospital much attention has been concentrated on the elaboration of new carcinogenic agents and on experimental therapy. Since experience has shown that therapeutic results obtained in transplanted tumours are often inapplicable to spontaneous growths, a strain of mice has been obtained which have a high incidence of mammary cancer. The success reported last summer to the International Conference on Cancer organised by the Campaign (see THE LANCET, 1928, ii., 173) in the production of a chicken sarcoma from injection of normal pancreas could not be repeated, and it is believed that similar failure has attended the efforts of the other experimenters who produced sarcoma from virus-free material. The technique involved in work on the Rous sarcoma is so intricate that no conclusions can fairly be drawn from isolated experiments, and it will be remembered that neither Dr. A. LEITCH nor Dr. J. B. MURPHY made any claims when recording their curious results. The premature and embarrassing clamour with which these were greeted is an indication of the intense desire of the public to hear news of good progress in cancer research. 'Organisations formed to promote research are faced with the dilemma that any hint of optimism is exaggerated by this desire, while when the cautious tone appropriate to reports of unconfirmed work, however stimulating, is adopted, the public is not impressed with the need for funds. The need is, however, urgent. The total amount of money spent by the Campaign during the past year on research work is approximately £24,000. While the expenditure is steadily increasing, the income from donations and subscriptions is not. Strong local committees, such as those established in Yorkshire, Lancashire, Cheshire and North Wales, Nottinghamshire and Birmingham are creating much interest, and are most valuable assets, but a large proportion of the funds collected in any of these districts is retained for the local research centres. Doctors are in a position to stimulate generous gifts by explaining the need for caution in presenting results and by *interpreting to their lay friends the sober yet hopeful* messages contained in this report.

Annotations.

"Ne quid nimis."

THE KING.

THE King's departure for Sandringham was fixed for Monday last, but in the morning its postponement was announced and an explanatory statement was issued over the signatures of Sir Stanley Hewett, Dr. Henry Martyn, Sir Hugh Rigby, and Lord Dawson. After giving the reassuring news that His Majesty was not *fatigued* by the Thanksgiving Service on the *previous* day, and that his general health was good, they stated that "the condition of the sinus in the right side of the chest has not made satisfactory progress," and that a further examination with X rays was proposed. The last radiological investigation, undertaken not quite four weeks *ago*, revealed one or two minute sequestra in the abscess *cavity* which had *formed* at the site of the rib-resection *performed* in December. Fresh radiograms have now been taken by Dr. Graham Hodgson, but it is *not* yet clear whether further local treatment will prove necessary, and until this doubt is resolved the King naturally prefers to remain within easy reach of his medical advisers. In any case there is fortunately no reason for renewal of anxiety.

THE FOURTH IMPERIAL SOCIAL HYGIENE CONGRESS.

THIS Congress, which was organised by the British Social Hygiene Council, was formally opened on Monday in the Livingstone Hall, under the presidency of the Marquess of Linlithgow. The problem of venereal disease being international as well as national, it was fitting that such bodies as the League of Red Cross Societies, the League of Nations, and the International Labour Office should be represented, and the presence of representatives of the Dominions and Colonies testified to the importance attached by them to the campaign against venereal disease. It became evident early in the Congress that the British Social Hygiene Council has established an extraordinarily close liaison with even the most remote corners of the Empire, and the large number of delegates from India was plain evidence of the interest taken in venereal disease in that country. International and Imperial congresses are usually rather impersonal affairs; they suffer from an atmosphere of austerity which the efforts of the most human of chairmen seldom succeed in mitigating. On this occasion, however, the meeting seemed more like a gathering of a clan, whose members were already well known to each other, than a formal congress, and the discussions which followed the papers revealed—one might almost say betrayed—a frankness to be found more often in the bosom of a family than in the precincts of a public building. The chairman's request to the press towards the end of the first meeting that it should withdraw in order to encourage freedom of speech did not, when the Congress was left to itself, yield a crop of candid and lurid speeches. Not a bit of it. Evidently the time has passed when the men and women engaged in the campaign against venereal disease feel that they must maintain a genteel silence, "yea even from good words," and some of the questions put to those who had read papers were as fearless as they were searching. Perhaps the most interesting of these questions was raised by a woman who asked: "What, in your opinion, is the effect of preventive outfits on the morals of the young men on whom they are bestowed?" It was not a question easy to answer offhand, and the person to whom it was addressed evidently thought that discretion was the better part of valour. But later in the same meeting the chairman, Mr. E. B. Turner, when summing up the main features of the discussion, took up the challenge of this question, answering it in unequivocal terms. To give point to his opinion he told the Congress of a young officer who had contracted syphilis and who believed the preventive outfit, giving him the thought that he was safe, had induced him to let himself go. At the meeting on Tuesday morning the discussion largely resolved itself into an advocacy, by speakers north of the Tweed, of compulsory measures in connexion with treatment. Some account of the proceedings will be given in a later issue.

THE CRESCENDO MURMUR OF MITRAL STENOSIS.

THE hypothesis that the crescendo murmur in mitral stenosis is attributable to auricular systole has been generally accepted since Mackenzie drew attention to the characteristic alteration which takes place in the physical signs when auricular fibrillation supervenes. Occasionally, however, even in the presence of fibrillation, the obstructive murmur appears to have a definitely crescendo character. Mackenzie himself referred to such cases, and put forward a tentative suggestion that in them the murmur was produced in a different way—namely, by slight regurgitation at the mitral orifice. This explanation is unsatisfactory, and on reconsidering the whole question Eggleston[1] comes to the conclusion that the apparent crescendo character of the murmur is an aural illusion, depending on the accentuation of the first heart sound. As many previous workers have pointed out, when the heart-rate is slow the obstructive murmur in fibrillation terminates before the end of diastole, and is then diminuendo in character. When, however, two heart cycles follow one another in rapid succession, the murmur fills the whole of diastole, and is continuous with the first heart sound. It is only under these circumstances that it appears to have a crescendo character.

DENTAL SURGEON'S LIABILITY FOR WATER-SUPPLY.

IT seems a little ridiculous that a dental surgeon should be liable to a special charge for water-supply in respect of the water used at the chair in his consulting-room. The Manchester Corporation has, however, recently succeeded in a claim of this kind. The legal position varies in different districts since water-supply is mostly governed by a special Act of local application. The undertakers are usually required to supply houses with domestic water at a charge depending on the rateable value of the premises, and are usually allowed to supply water *for trade and non-domestic purposes on such terms* and conditions as they think fit—normally by meter at special rates. In 1863 the Waterworks Clauses Act gathered up in one convenient code a set of model clauses which are often incorporated in local legislation about water-supply. Section 12 of the 1863 Act explains that "domestic purposes" do not include water-supply for cattle or horses or washing carriages or horses where the carriages or horses are kept for sale or hire, or supply for any trade, manufacture, or business, or for watering gardens or for fountains or any ornamental purpose. But, as already stated, the law in a particular town depends upon the local Acts which operate in that area, and, even when the Acts are studied, the principles are not too easy to apply. If the courts are asked to distinguish between water-supply for domestic purposes and water-supply for a trade, business or profession, what test are they to apply? Even if a trade or business is carried on in a house, the persons in the house must be entitled to water for domestic purposes. It is not enough, said Lord Dunedin in Metropolitan Water Board *v.* Avery, to argue that a trade is carried on in the premises or that the people who use water on the premises only go there because a trade is carried on. The test is the purpose for which the water is used, not the character of the premises. Lord Dunedin rejected the alternative test, which would suggest that every use of water, however domestic in its nature, which appears as a step (however insignificant) in a trade operation, must be use of water for a trade and therefore not for domestic purposes. In Avery's case the Metropolitan Water Board admitted that they did not charge public-houses at more than the domestic rate, though the nature of the business must involve constant washing of mugs and glasses. It would be absurd, said Lord Dunedin, if a shopkeeper could not even wet a sponge to clean dusty goods without being liable for water at a trade rate. The true test, therefore, is not whether water is used in the course of the trade, but whether the use is in its nature domestic or not.

In the recent Manchester case, the plaintiff corporation contended that the dental surgeon, using the water in the course of his practice, was carrying on a trade or business within the meaning of the local Acts applicable, alternatively that the water used at the dentist's chair was used for other than domestic purposes. Mr. Justice Eve ruled against the corporation on the second of these alternatives, but decided in favour of the corporation upon the construction of the language of the special Manchester Corporation Waterworks Acts because one of those Acts provided that the corporation need not supply any dwelling-house with water

themselves indications for operation in the early stage of the disease; and he furthermore believes that, in spite of radical exenteration of the mastoid, early operation offers no guarantee against late complications. On the other hand, Prof. Haymann regards the outlook as very different when the acute stage of the middle-ear inflammation has passed and there are symptoms pointing to localisation of suppuration in the mastoid. Here the prospect of recovery without operation is much less and the danger of endocranial complications very much greater. An exact time-limit is impossible to fix, but he considers that the period when mastoid symptoms acquire a serious aspect is somewhere after the second week from the onset of the acute middle-ear inflammation. Again, the persistence of a profuse creamy purulent discharge, lasting, say, six weeks, is an indication for operation in the absence of all other symptoms. He draws attention to the group of cases in which all symptoms are absent except that the membrana tympani remains somewhat thickened and the diminution of hearing persists; in these cases, usually due to infection by *Streptococcus mucosus*, extensive bone disease is often found at operation, particularly where the patient is over 40 years of age. Prof. Haymann supports his conclusions by statistics of 791 cases of acute otitis treated on these principles. Among them there were 25 deaths attributable to disease of the ear, and of these 7 were in patients brought to hospital in an advanced stage of neglected disease. These results are so good that his contention deserves the careful consideration of otologists.

THE HEALTH OF THE NAVY.

As the Statistical Report of the Health of the Navy for 1927 has now appeared [1] it can be stated that the illness and mortality-rates per 1000 in the three Services in that year were as follows: Navy, cases 479·05, deaths 2·15; Army, cases 467·7, deaths 2·42; Air Force, cases 467·8, deaths 4·15. The Navy health report provides evidence of considerable improvement, for it claims the lowest death-rate from all causes yet recorded, and a death-rate from disease (1·36) equal to the lowest, which was in 1925. The death-rate from injury (0·76) is notably low, being about a quarter of that of the British seamen in the merchant marine in the same year. There were in the Navy in 1927 92,230 men, and, as we have stated, the incidence of disease and injury per 1000 was 479·05. There were more numerous cases of influenza and respiratory diseases than in the previous year, but many fewer of the infectious fevers, and it is notable that there were 36 fewer cases of tubercle of the lung (151 in all). Invaliding was less at 13·8 per 1000 (18·12 in 1926), the chief causes being errors of refraction 234, ear disease 199, and tubercle of the lung 159. For refusing surgical operations only 37 were this year invalided, 10 fewer than in 1926, which shows the increasing confidence of the men in their medical officers. Deaths were also reduced to 2·15 (from 3·18 in 1926), the chief causes of death being drowning 27, injuries 25, and tubercle 20. Enteric fever cases were slightly increased to 18 (2 deaths); one of the cases was that of a medical officer who contracted paratyphoid in a laboratory. Influenza (2562 cases with 1 death) attacked chiefly the Home Station, the incidence there being three times as great as in the fleets abroad. Pneumonia and rheumatic fever slightly increased. Pulmonary tuberculosis again decreased, and especially at ages above 25. Under 25 the tuberculous cases invalided were 62 this year as compared with 67 last year; over 25 they were 97 as against 114. Ages are classified this year in five-year groups, as they should be in all such statistics if the figures are to be readily compared with those published by other organisations. But why are the "cases" in Table III. (p. 12) given as 143, and in Tables I. and II. as 151, as also on p. 72? Last year they were 187 everywhere. Tubercle of the lung shows more cases in the "service afloat" (1·7) than on the Home Station (1·45); its incidence on ships' cooks is remarkable (4·45). Cases of venereal disease have slightly decreased; local disinfection with calomel cream and mercuric iodide soap is always available, recreation is encouraged, and warnings are seriously given. The period of treatment for gonorrhœa has decreased by two days per case. More dental officers were available, so more teeth were conserved—63,716 against 58,527. We miss in these brief statistical reports the often interesting stories of medical officers about their experiences—so noticeable a feature in the past—but we are this year given account of an outbreak of beri-beri in a sloop doing an extended tour in the Persian Gulf in summer. Four Europeans and four natives were affected. Fresh vegetables could not be procured, there was little fruit, and much of the food came out of tins. Disinfection was carried out weekly, unpolished rice was issued, dried peas were soaked for 48 hours before cooking (it is not stated that they were allowed to germinate), and yeast was given. Only teetotallers were affected, and only the local beer is mentioned as having had a possibly curative influence on the disease. It will be recalled by students of naval medicine that fresh vegetables and beer are supposed to have maintained the health of Lord Hawke's fleet in 1759 before the Battle of Quiberon Bay Among the cases then spoken of as scurvy were there perhaps some that were really unrecognised beri-beri? Much research work was done in 1927 at the Royal Naval Medical School, Greenwich, on oxygen analysis, swimming-bath water, regeneration of air in submarines, and vaccines; also what is described as "a lot of laborious" experiments on the testing of disinfectants. The Marines at headquarters are still excluded from the summary of the total force (pp. 13 and 72), but their invalids are included on pp. 20–23. There is still no sanitary report on the cadets at Dartmouth, and we are sorry to see that the price of the Report has been raised.

"WITHIN THE RANGE OF MEDICAL SERVICE."

AN inquiry has been held at Manchester upon the question whether treatment of varicose veins in the leg by intravenous injection of a sclerosing solution is within the range of medical service as set out in Article 43 of the Medical Benefit Consolidated Regulations of 1928. This treatment was administered in May, 1928, to a female insured person by her panel doctor of Manchester, and both the local insurance committee and the local medical committee were in agreement in holding the view that it was outside the range of medical service. The matter being referred to the Minister of Health, Mr. E. H. Tindal Atkinson (Barrister-at-Law), Dr. E. Collingwood Andrews, and Dr. Alexander Forbes were asked to inquire and report. For the purposes of this inquiry the treatment is thus briefly described.

> The vein is punctured by a hypodermic needle attached to a syringe and into the vein is injected a pre-determined quantity of sclerosing solution. The solution has the effect of forming an adherent clot in the vein which ultimately results in obliteration. A number of injections may be necessary in accordance with the length of the vein requiring treatment. Particular care has to be exercised to avoid the entry of air into the vein and to ensure that the solution shall pass only into the vein and not round it or into the adjoining tissues. The most ordinary solutions in use are sodium salicylate and urethane and quinine and urethane.

No question was raised as to the possession by the panel doctor of special skill qualifying him to administer the treatment and the referees assumed that he did in fact possess such special skill. On behalf of the Minister it was contended: (1) That the operation is not difficult or dangerous. (2) That as compared with the taking of blood for the Wassermann test the operation can as certainly be regarded as within the range of medical service. (3) That knowledge of the technique can be acquired from text-books and requires no particular training either in the actual administration of the treatment or in the judgment requisite to decide on the advisability of its use. (4) That the treatment, while admittedly modern, has become so well known that any ordinary practitioner should in a proper case be prepared to adopt it. (5) That the risks of any adverse effects are negligible in the light of statistical knowledge. On behalf of the insurance and panel committees it was contended: (1) That a considerable degree of skill is required at least equal to that necessary for the injection of salvarsan or its substitutes, particularly also where ulceration is present. (2) That at the present time there has not existed sufficient experience of the treatment and its results to justify its inclusion in the range of medical service. (3) That there are many contra-indications against the treatment—e.g., it is dangerous in the case of a pregnant woman or in certain cases where heart disease or high blood pressure is present or in the case of patients who have some idiosyncrasy to quinine or salicylate. (4) That the standard of skill in the Manchester locality is such that the treatment may fairly be regarded as special and not of such a character that it should be carried out by the ordinary insurance doctor. (5) That statistical knowledge as to after-effects is not sufficiently established.

---

[1] H.M. Stationery Office. 1929. Pp. 147. 5s.

The referees found for the Minister. While admitting that injection treatment of varicose veins is modern, they note that it is now practised with success in a very large number of cases. The technique is not difficult and any panel doctor should be able to decide whether the patient is a fit subject for the treatment. There may be no substantial difference in the actual technique of the two injections, but the referees thought the possible risks attendant upon salvarsan treatment to be such as to render it not fairly comparable with injection for varicose veins. Two of the referees, however, felt that when the treatment was actually applied in Manchester in May, 1928, it might then have been regarded as in an experimental stage, although this was no longer true at the time of the inquiry.

THE AMERICAN COLLEGE OF SURGEONS.

THE nineteenth annual Clinical Congress of the American College of Surgeons will be held in Chicago on Oct. 14th and the four following days under the presidency of Dr. Franklin Martin. All departments of surgery—general surgery, gynæcology and obstetrics, and the main special branches of surgical practice—are represented in the programme, and demonstrations will be given in the laboratories attached to the hospitals and schools of the four great universities of the city, the Northwestern University, the University of Chicago, the University of Illinois, and the Loyola University. On the first day of the session the President-elect, Dr. Merritte Ireland, Surg.-Gen. U.S.M.C., will be inducted into office and deliver the annual address, after which Mr. D. P. D. Wilkie will deliver the Murphy Oration.

An important feature of the meeting will be the Hospital Conference, in connexion with which great efforts have been made to present short papers and practical demonstrations dealing with many questions of hospital efficiency, and it is hoped that round-table discussions on the various problems will be of service not only to the scientific staffs of the institutions, but to hospital trustees, boards of management, and directorates. The Conference will open as soon as the College is in session, its proceedings taking place in the grand ballroom of the Stevens Hotel, where the general headquarters of the Congress will be established.

Attendance at the Congress [illegible] to a number that can be comfortably [illegible] in their groups at the various clinics, [illegible] be necessary for visitors to register in advance their intention to be present. The executive body in Chicago has for chairman Dr. L. Kretschmer, and secretary Dr. Loyal Davis.

COMPOUND COMPOSITE ODONTOMES.

THE study of odontomes is one of the most fascinating branches of dental pathology. Mr. A. T. Pitts has recently described to the Royal Society of Medicine[1] three of those rare types known as compound composite odontomes which, under Sir John Bland-Sutton's classification, were called compound follicular odontomes. The first case occurred in a boy aged 15, and the odontome was found in the region of the right upper canine and the adjoining premolars. It appeared as a hard irregular swelling about the size of a filbert nut. Clinical examination, even with the aid of a radiogram, did not enable Mr. Pitts to determine whether it was a complex or a compound composite odontome. At the operation, however, 18 separate denticles were discovered. No definite capsule could be found surrounding the whole tumour; but some of the denticles appear to have had an investing membrane, whilst others were embedded in fibrous tissue. One of the calcified masses contained enamel, dentine, and cement. The dentine was well formed; but the enamel, as so often happens when it is found under pathological conditions, was granular. In another denticle, from which a section was obtained, no cement was found. The largest piece consisted of four or five denticles fused together in an irregular mass. In all of the larger denticles radiograms showed evidence of the presence of a pulp canal. The second case was that of a boy aged 3 years and 8 months, who presented a hard rounded swelling in the region of the right upper deciduous incisors which had failed to erupt. A mass of nine denticles could be seen in the radiogram; and, in this case, a correct diagnosis was made before the operation. The missing deciduous central and lateral incisors were in close relation to the denticles which were enclosed within a capsule and the latter was continuous with the tooth sac of the first deciduous incisor. The permanent incisors were lying above the swelling. The largest denticle consisted of a trituberculur crown with a single stunted root. The other denticles resembled conical teeth. The third case occurred in a boy aged 14, and this presented six supernumerary teeth in the left upper first premolar region. The boy gave a history of having himself removed four supernumerary teeth from the same region, previous to his visit to a dental surgeon for treatment.

It is a moot point whether this last case should be classed with odontomes at all. Many pathologists would not have placed it here. But the line of demarcation between abnormally formed teeth and odontomes is by no means clearly defined. Long ago, Albrecht taught that tumours are malformations, and that it is not always possible to distinguish new growth from development. Prof. G. W. Nicholson also regards tumours as aborted organs. Mr. Pitts himself puts forward several suggestions. First, he raises the question of the possibility of odontomes erupting like ordinary teeth. There seems to be no reason why they should not do so, provided the conditions correspond with those which are essential for the eruption of a tooth. Undoubtedly, many odontomes do pass through this process; but others remain embedded within the jaw, or only become exfoliated as a result of suppuration and necrosis of the overlying bone. When the epithelial remnants of the tooth band (which Mr. Warwick James has described as the determining factor in directing the tooth to its final position in the jaw) remain in their correct relationship, the odontome may erupt like a tooth. But the aberration which leads to the formation of a tooth tumour often involves these epithelial structures; and then, if the becomes exposed to the surface it may be a process of exfoliation rather than one of eruption. Mr. Pitts also refers to the manner in which one type of odontome may blend with another type. Many pathologists who have investigated these tumours recognise this fact and it is this which makes the classification of some cases very difficult. In his first case four or five denticles were fused together in one mass, but so long as the minute structures of denticles are not inextricably mixed up with one another there is no reason for considering this mass to be a *complex* composite odontome. Some years ago Bland-Sutton described the case of a woman who "spat out" a mass, consisting of dental tissues fused together, which appeared to be a collection of independent denticles united by cement and might well be included under the group called compound composite odontomes, rather than under the complex composite odontomes. On the other hand, some of the individual denticles contained within a compound composite odontome may be of the complex composite variety. With regard to the third point which Mr. Pitts raises on these cases, it seems evident that an odontome may arise from the original tooth band; or may be due to an aberration of the deciduous or the permanent tooth germ, or to that of a supernumerary tooth. Very few compound composite odontomes have been fully recorded, and all who are interested in the study of odontomes must feel grateful to Mr. Pitts for the very careful manner in which he has described these cases.

[1] Proceedings of the R.S.M., 1929.

XIIITH INTERNATIONAL OPHTHALMOLOGICAL CONGRESS.

It will be timely to remind any who propose to attend this Congress, which will be held at Amsterdam from Sept. 5th to Sept. 13th, that if they will send their subscriptions now it will greatly facilitate the work of the National Committee. We learn that 700 members have already been enrolled and that 232 communications, covering all branches of ophthalmology, have been promised. It is certain, therefore, that those who find themselves unable to be at the meetings will find it extremely useful to possess the Transactions, which promise to form a compendium of recent work in ophthalmology. So those who cannot go to Amsterdam will reap a real advantage by becoming members of the Congress, when they will be supplied with a copy of the Transactions as soon as they appear. The subscriptions (25 Dutch florins = £2 2*s.* English money) should be sent to Dr. H. M. Roelofsz, Director of the Incassobank, Heerengracht 531, Amsterdam.

On the recommendation of the Minister of Health, the King has been pleased to appoint Dr. Bedford Pierce to be a temporary Commissioner of the Board of Control.

Lord Dawson has been re-elected President of the Royal Society of Medicine for another year The hon treasurers for the year 1929–30 are Dr. A. M. H. Gray and Mr. W. Girling Ball; the hon. secretaries Mr. E. K. Martin and Dr. George Riddoch; the hon. librarians Dr. William Bulloch, F.R.S., and Mr. H. W. Carson; and the hon. editors Dr. Hugh Thursfield and Mr. J. Swift Joly.

Sir Albert Levy has set aside £250,000 to form a fund for the support of hospitals and other charitable objects. The whole of this sum, plus interest, will be distributed "in 25 yearly instalments," the total amounting to about £400,000, of which £100,000 has already been allocated for hospital purposes. A division of one twenty-fifth part of the capital and income will be made on May 1st and Nov. 1st of each year, and communications may be addressed to the secretary of the Albert Levy Benevolent Fund at 5, St. James's-place, London, S.W.1. Sir Albert is treasurer of the Royal Free Hospital, to which he has lately made two gifts of £50,000 each.

The Clinical Interpretation of Aids to Diagnosis.

A Series of Special Articles contributed by Invitation.

XXXVII.

CHARTS OF FRACTIONAL TEST-MEALS.

Part II.*—Abnormal Curves.

Charts Showing High Acidity.

In Fig. 3 and Fig. 4 are given examples of typical charts showing high acidity. It will be seen that in both of them there are *at least* two readings of free HCl above 50. When this is encountered it is always true to say that the case is *probably* from a pathological subject, although, as was noted last week, such a chart is occasionally encountered in a healthy person. Fig. 3 shows a rapidly rising curve of acidity with rapid emptying of the stomach, which is more frequently encountered in cases of duodenal or juxtapyloric peptic ulcer than in any other condition. It is, therefore, correct for the pathologist to report that the chart is suggestive of such a condition. It must be emphasised that neither this nor any other type of chart can ever be conclusive evidence of the presence of an ulcer.

Fig. 4 differs from the preceding one in that the curve of acid (both free and total) rises slowly without perhaps reaching such a high concentration as in the last condition. It is typical of what is sometimes called the "climbing curve"—i.e., there is no drop in the acid in the later stages, probably because spasm or obstruction of the pylorus is preventing the free regurgitation of alkali through the duodenum. Such a chart is characteristic of many cases of gastric and juxtapyloric ulcer, and suggests that without such a degree of irritability of the stomach as is present in cases producing Fig. 3 there is some impediment to the pyloric outlet.

In Fig. 5 is shown a chart of the "Plateau" type which is characteristic of pyloric obstruction. Such a chart would be prolonged for three hours or longer, depending on the patience of the subject and observer, and if the stomach is completely emptied at 2½ hours, the amount of contents recovered at that moment will probably considerably exceed 100 c.cm. Such a chart is diagnostic of pyloric obstruction, and it will further be noted that in such cases the concentration of HCl is seldom so high as in the cases discussed previously, and that there is a greater disparity between the curves of free and total acidity owing to the presence of organic acids resulting from fermentation.

Low Acid Charts.

Fig. 6 is a typical example of complete achlorhydria of the "benign" type. There is complete absence of HCl and total acidity is also low. Emptying is usually rapid and may be very rapid. It would be beyond the scope of the present article to discuss at length all the possible interpretations or causes of such a chart, but the following points must be emphasised:—

1. It occurs in about 5 per cent. of normal healthy men.
2. It is present in probably every case of pernicious anæmia.
3. It is occasionally, but somewhat uncommonly, present in cases of cancer of the stomach.

Apart from such cases of complete achlorhydria, cases are sometimes met with in which there is a trace of free HCl at one or two readings only. Great hesitation must be observed before considering any such chart as indicative of a pathological condition. It is a very common finding in perfectly healthy people who are nervous or who have been upset by

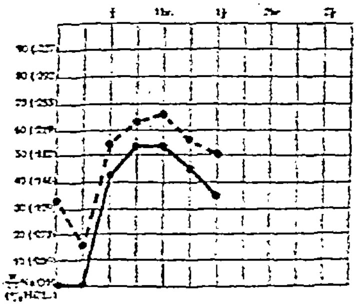
FIG. 8.



Showing free secretion of acid with rather rapid emptying.

the difficulty of swallowing the stomach-tube. In my opinion the most that can ever be said of such a chart is that it suggests some interference with the proper secretion of gastric juice. The laboratory worker is never justified in proceeding to give reasons for such an interference, which may be congenital, acquired, organic, or functional. Further, it may be said that such a result should be obtained on more than one examination before it is accepted as a constant finding in any subject.

Charts Found in Cases of Gastric Carcinoma.

Gastric analysis finds perhaps its most useful application in the diagnosis of cancer of the stomach. Reference to the text-books reveals a diversity of opinion as to what the findings are in cases of this disease. This is due to the fact that gastric cancer does not give a constant picture either to the clinician, the radiologist, or the laboratory worker, it being a disease the manifestations of which vary according to the nature and exact situation of the neoplasm. Small growths obstructing the pylorus will necessarily produce an entirely different picture from diffuse growths of the body of the stomach, and the leather-bottle stomach, now generally accepted as malignant, will give a picture to the analyst entirely different from that seen with a growth which is discharging a profuse mucoid secretion.

Controversy with regard to the findings of gastric analysis of cases of carcinoma of the stomach usually centres round the question whether or not free HCl is found. It may be said at once that this criterion is of little diagnostic value, as from 40–60 per cent. of cases of gastric carcinoma will show a certain amount of free HCl if proper precautions are taken for demonstrating it. A second point which has occasioned much controversy is the significance of the presence of lactic acid. Nothing dogmatic can yet be stated on the subject beyond the fact that lactic acid is not invariably present in cases of cancer of the stomach, and is occasionally present in cases without any malignant disease.

To proceed from these facts to the assumption that gastric analysis is of no diagnostic value in cancer of the stomach is a profound mistake, gastric carcinoma being capable of detection by this method probably in as great a proportion of cases as when X ray examination alone is made.

The following are, in my opinion, the most frequently occurring types of chart encountered in this condition:—

1. The "benign" achylia described above and illustrated in Fig. 6. In cases of carcinoma of the stomach, this chart will differ from that seen with pernicious anæmia, owing to the fact that (*a*) blood tends to be present in the fasting juice and in later specimens, (*b*) a profuse secretion of mucus is often found, and (*c*) emptying is not, as a rule, as rapid as in cases of true benign achylia.

2. Charts showing low or absent free HCl, but a considerable concentration of total acidity. An example of this type of chart is given in Fig. 7. The fasting stomach content in such cases is nearly always abundant, often foul, and frequently contains partly digested food. It can be made more obvious by giving the patient one or two charcoal biscuits to eat late in the evening prior to examination. Fragments of charcoal are then demonstrable when the stomach is emptied on the following morning. It is frequently almost impossible to empty the fasting stomach in these cases, and the high total acidity with absence of free HCl in subsequent specimens is due to the fact that the meal has been swallowed into a stomach which still contains stagnant contents. It is owing to the fact that such contents have not been washed clear of the gastric mucosa that the test-meal fails to provoke a secretion of HCl after it is swallowed. Food, often partly digested, is frequently present in all specimens. The whole chart is really a picture of gross pyloric obstruction, a condition which is almost invariably the result of a new growth in that region.

3. Fig. 8 is taken from a case of cancer of the stomach in a young patient. It shows a free secretion of acid with rather rapid emptying, and by itself gives no clue to the diagnosis. It will, however, be observed that in the fasting stomach the contents show no free HCl, but a relatively high total acidity; in actual fact 40 c.cm. of fluid containing much mucus, altered blood, and fragments of charcoal, and having a foul smell, constituted this fasting stomach specimen and enabled a diagnosis to be made with some certitude. Without constituting a characteristic group as regards the shape of the curve, cases of this type are characteristic of an appreciable percentage of examples of cancer of the stomach and illustrate the importance of warning the observer in advance of the diagnosis which it is sought to confirm, as only by this means may the necessary data be obtainable.

General Conclusions.

It is hoped that study of what has been written above will convince the reader that whilst fractional gastric analysis is by no means the short-cut to definite diagnosis which it has been imagined to be in certain quarters, it is, if carefully carried out, an extremely valuable aid to the diagnostician. It differs from the majority of laboratory procedures in that it is essentially an inexact method from which conclusions can only be drawn by paying attention, not to chemical accuracy alone, but also to careful technique in the collection of the specimens and critical moderation in the interpretation of results. In my view, fractional gastric analysis should be a *clinical* more than a laboratory method of examination. It involves the expenditure of a considerable amount of time by both the patient and the observer, and it is only when both parties are prepared to make this sacrifice that valuable results can be obtained with any frequency.

T. IZOD BENNETT, M.D., F.R.C.P. Lond.,
Physician to Out-patients, Middlesex Hospital.

The Services.

ROYAL NAVAL MEDICAL SERVICE.

Surg. Comdr. F. G. Goble is placed on the Retd. List with rank of Surg. Capt.

ROYAL ARMY MEDICAL CORPS.

Lt.-Col. A. C. H. Gray to be Bt.-Col.

Maj. C. M. Drew to be Bt. Lt.-Col.

Maj. N. Cantlie is placed on the half-pay list on account of ill-health.

ARMY DENTAL CORPS.

Capt. W. R. Wotton to be Maj.

TERRITORIAL ARMY.

Maj. J. Ramsay to be Lt.-Col. and to comd. 12th (2nd Western) Gen. Hosp.

TERRITORIAL ARMY RESERVE OF OFFICERS.

Lt.-Col. (Bt. Col.) D. Dougal from Active List, to be Lt.-Col. (Bt. Col.).

ROYAL AIR FORCE.

Group Capt. J. McIntyre to be Air Commodore.

Wing Comdr. J. MacGregor to be Group Capt.

Squadron Leader P. M. Keane to be Wing Comdr.

Flight Lts. J. K. R. Landells and E. D. D. Dickson to be Squadron Leaders.

Flight Lt. E. E. Isaac to be Hon. Squadron Leader.

INDIAN MEDICAL SERVICE.

Maj. Mohamed Abdur Rahman to be Lt.-Col.

COLONIAL MEDICAL SERVICES.

The following appointments have been made: Dr. C. J. Boyd, Medical Officer, Federated Malay States; Dr. W. G. MacNaughton, District Medical Officer, Fiji; Dr. H. A. MacMillan, Medical Officer, Kenya; and Mr. L. L. Burton, Colonial Surgeon, St. Helena.

Special Articles.

THE FUTURE OF MEDICAL PRACTICE.

AN ADDRESS BY LORD DAWSON.

IN the course of an address delivered when distributing prizes to students at the London Hospital Medical College on June 28th, Lord Dawson said:—

It is only natural that you should be dazzled by the fascinating unfolding of all that radium is telling us, following as it does upon the steady progress of discovery in biochemistry, in radiology and other sciences; but the very dazzle of this discovery has dangers, because I would remind you that you are going to be men of action; you are going to come in contact with the sick, and all the results have to be judged by the criteria of the bedside. In order to learn disease as it affects mankind you must study mankind. Disease is not a standardised product; for, thank heaven, man preserves his individuality in sickness as well as in health; otherwise it would be an uncommonly dull world to live in. Therefore, if you are taking a history and are not a little bored at the tedium, and inclined to say "Why cannot the Lab. do this for us?" my urging to you is "Don't." Take the trouble. For every moment of it you will be rewarded. There you are learning how symptoms vary and what they stand for, not only in the abstract, but in *that* patient. You are gaining insight and perception and not only knowledge but understanding, and you are thinking of life not in terms of remedies but in terms of healing.

Now I come to what I think must interest you all most—namely, the future. That is the direction in which all eyes should look, for we live in an astonishingly interesting world which is going to show great changes. I would beg of you not to listen to the croakers who can be heard all around. The people who croak are those who are mistaking change for decadence. The great need of England to-day, as I see it, is that young men and women should think, and, having thought, help to direct the course of the nation. That is true of the profession of medicine as it is of other walks of life. The teaching of medicine in Britain to-day is very well done, but we do not give the world a very good opportunity of seeing that it is well done. If visitors come they see, but we do not put our goods much in the shop window—perhaps not enough. For research we are rich in brains, and increasingly rich in opportunity. All schools and universities are fully alive to the importance of the extension of knowledge; and I would like to say here that in the coördinating of effort and for encouragement we owe a tribute to the Medical Research Council.

It is to the field of general practice that we need to pay attention, for it would be a sorry day for any country were general practitioners to become weak in their work or their influence. *This is now a danger* in certain countries of the world.

The practitioner is one of our protectors against the "stunt" specialist. Only the other day an American lady said to me, "If I get an acute sore-throat I have no one to tell me what to do with it. Three specialists come in one after the other; one with a laryngoscope, the next to take my blood, and the third to take a culture, and by the time they all report I am either better or dead."

Again, it is to the interests of the community to identify the practitioner with the health of the people and to give him this career.

I will put *certain questions* to you. *Is it not a* fact that practice is becoming grouped around occupations and social needs, and less located in the home? The needs of the expectant mother, care of the child, the treatment of tubercle, are all examples of the classification of practice round needs. The uprising of medical and welfare services in the hives of industry is a striking development which deserves the attention of all doctors who have their lives in front of them. Think what these places offer. They are provided with clinics, with hospitals, and even with laboratories. There they look at the workpeople, and test their fitness for this or that kind of work, thereby not only securing better output, but saving an unjust burden being put upon the backs of men whose physique is unsuited to bear it. You have only to go through the wards of this hospital, and time and time again you see a poor man about 40 or 50, nothing else wrong with him but this—and a grave wrong it is—that he has been a blacksmith or a lighterman when nature meant him to be a tailor. That fitting as regards employment—fitting the round peg into the round hole—is a duty that should come under the mantle of the medical profession.

Further, is it not plain that more clinic and hospital provision is needed? You cannot afford to allow this question to rest. By a recent Act of Parliament the local authorities throughout this land are taking on a new chapter in their work and responsibilities in regard to the sick. They have the power to found clinics and hospitals. I wish to put this before you: Clinics and hospitals must not only be thought of in terms of great teaching institutions like this. They are required everywhere—though varying in size and the simplicity and complexity of their functions—and to some of them general practitioners should have access. Thus there would follow what we want to see: fewer visits and better opportunities for good work at each visit.

I beg of you, therefore, to give these questions your careful attention, and to see to it that in the shaping of the health policy of this country regard is had to them. It is said that the problem of general practice, *in its relation to hospital provision and the* problem of how to treat patients of limited means, has been solved in Germany and the United States. I tell you it has not been solved anywhere. It remains for this country to do so, but success in that direction will depend upon the vigour and the worth of the younger medical men who are coming to the fore. By the securing of better opportunities, by responsible contact with the health organisation of local government, I think you will find that the centre of gravity of your work will move towards prevention and early diagnosis, and that you will rise up as the interpreters of health to the people.

MEDICAL PRACTITIONERS AND MOTORISTS.—In our last issue (p. 50) we referred to the *Manchester Guardian's* recent questionaire on payments to hospitals by motorists injured in road accidents. The same newspaper has since published replies received from medical men practising in or near Manchester showing "that the skilled attention which the general practitioner gives to victims of motor accidents too often goes unrewarded and even unacknowledged." One writer reports having treated 13 cases without receiving any fee. Another says that he is seldom paid by casual persons involved in motor or motor-cycle accidents. Moreover, *it is not usually worth while to take action to* compel payment, for it would cost as much as the actual cost of treatment. Another doctor finds that when the patient is not one of his own clients payment for services rendered is frequently very difficult to obtain, especially from motor-cyclists, who are often uninsured against accident. The same experience applies to all casual street accidents, however caused. Additional replies from hospitals include one from the Royal Infirmary, Glasgow, where during 1928 the number of in-patients treated suffering from motor accidents was 601 and the average cost per patient was £7 16*s*. and out-patients treated numbered 608. No charge was made for these cases, and very little was contributed by any injured person voluntarily. The infirmary suffers from having to treat these accidents to the amount of approximately £1600 per annum. The number of motor accidents admitted to the Cardiff Infirmary in 1928 was 233, and the total number of days in hospital was 1169. The amount contributed was only £138 and the total cost to the infirmary calculated at 8*s*. a day was £1067.

THE BRITISH AND AMERICAN ORTHOPÆDIC ASSOCIATIONS.

THE British and American Orthopædic Associations held a joint meeting in London during the first week in July.

The meeting was largely attended, many notable orthopædic surgeons contributing papers and taking part in the discussions. The proceedings in London opened on July 4th, when Prof. E. W. **HEY GROVES**, President of the British Orthopædic Association, took the chair and introduced Dr. **FRED ALBEE**, who gave an address as President of the American Orthopædic Association. He referred to high-speed tools in bone surgery and dealt at some length with the anatomical, physiological, and pathological principles on which their use is based. The Robert Jones Medal was presented to Mr. E. P. Brockman for an essay on Club-foot, after which Prof. E. W. Hey Groves (Bristol) resigned his place to Dr. Albee while he himself opened the discussion on

Treatment of Fractures of the Neck of the Femur.

Prof. **HEY GROVES** said that the most likely sources of error in treating these cases were: (1) to suppose that spontaneous impaction was adequate on the strength of X ray evidence alone, since this evidence is often fallacious; (2) to attempt reduction in elderly patients before the initial shock had passed off; (3) to take it for granted that such fractures are uncommon in the young and do not carry the risk of non-union early in life; (4) to think that it is not worth while reducing the fracture and splinting it adequately in old patients. He then asked those about to take part in the discussion to answer the two questions: What are the end-results of the methods in present use; and what are the best methods, and if more than one, when is each most applicable?

Dr. **ROYAL WHITMAN** (New York), the originator of the abduction treatment which is now recognised all over the world as the best conservative method, followed Prof. Hey Groves and pointed out that his own cases are largely selected ones, so that his statistics could not be regarded as typical. In answer to a question, he said he could only remember one case of non-union among all those he had treated, and his cases included persons up to 86 years of age. He showed lantern slides illustrating his method and deprecated the modifications introduced by various surgeons, who have overlooked the importance of its details. He stressed particularly the need for traction on the limb, to draw it out to the same length as the sound one, before any abduction was attempted, and also of maintaining full internal rotation and of making the abduction exactly equal to the maximum obtainable on the sound side. This implied that the limbs must be held symmetrical until the end of the application of the plaster. He insisted on the value of team-work and showed a photo of an old lady to whom he had applied the plaster-spica in 7½ minutes under ethylene anæsthesia. His routine was to keep the patients in bed for one month, with frequent changes to the prone position and attention to the skin of the back under the plaster. He then allowed them up on crutches in the plaster for another two months. At the end of three months from the application of the plaster, it was bivalved and two or three months careful physiotherapy was given with re-education of the muscles and mobilization of the joints in recumbency; finally, a walking-splint was used till the end of the first nine to twelve months from the accident, under which time firm union could not be expected.

Dr. P. D. **WILSON** (Boston) demonstrated a steel nail with cutting triangular shaft, which Dr. Smith-Peterson had designed and had used for several years to secure fixation of these fractures. He advocated early open operation in all cases in view of the high percentage of cases of non-union even with the best conservative methods, and he stressed the danger of permanent stiffness of the knee after use of the long Whitman spica.

Sir **ROBERT JONES** (Liverpool), while recognising the excellent results obtained by those who advocated surgical intervention, emphasised the importance of standardising and popularising some conservative method which was applicable under the less favourable conditions met with by general practitioners and surgeons in country areas, for only so would the general level of results improve.

Dr. **ALBEE**, Dr. **WILLIS CAMPBELL** (Memphis), and Mr. **BLUNDELL BANKART** (London) referred to the poor blood-supply of the head of the femur in producing non-union even under the best treatment. Other speakers deprecated the lack of any uniform plan of treatment of these cases in our big general hospitals, where some cases are splinted for a week or two only, which is obviously inadequate, while others are kept in plaster many months, with no attention to the condition of the muscles or joints and no supporting apparatus when the plaster is removed from the limb. It emerged from the discussion and the statistics presented by a number of speakers that, even with the best methods known at present, non-union is to be expected in about 30 per cent. of cases; some speakers placed it as high as 45 per cent. All those who advocated surgical intervention agreed that it was essential to expose the site of fracture and reduce the displacement before attempting to insert any fixation material.

In summing up, Dr. **ALBEE** emphasised the advantages of his method of using an accurately fitted screw of living, autogenous, vascular bone and quoted experiments which showed that the boiled beef-bone was not well tolerated. Prof. **HEY GROVES** in reply said that the advocates of steel and live bone-screws produced arguments which cancelled one another and he remained convinced of the virtues of his simple and speedy method with the beef-bone screw.

In the afternoon Prof. V. **PUTTI** (Bologna) gave a short paper on the

Early Diagnosis and Treatment of Congenital Dislocation of the Hip.

This paper was illustrated with radiograms of single and double dislocations in infants under one year, including one a day old, and also illustrations of the abduction cushion, by which he has gradually secured reduction in six to twelve months without any forcible manipulation. He dwelt particularly on the chief points in the X ray diagnosis—i.e., shelving of the roof of the acetabulum, absence, or poor development, of the bony nucleus of the femoral head, and increase of the distance between the upper end of the femur and the floor of the acetabulum, even when the neck is not raised above Shelton's line. As regards clinical diagnosis in infants under one year of age, he held that the medical practitioner ought to be at least as observant as the mother, who often noticed inequality of the skin folds on the inner side of the thighs; asymmetry of the outline of the hip regions on the two sides; deepening of the groin hollow; shortening of one limb; and possibly undue mobility of one hip, or its limitation by tight adductors. The presence of any of these features demanded an X ray examination. Prof. Putti remarked how satisfactory in bringing early cases to light had been the intensive propaganda undertaken in Italy among practitioners, nurses, and midwives, and the compulsory training of medical students in orthopædics.

Treatment of Common Spinal Conditions.

Dr. J. E. **GOLDTHWAIT** (Boston) gave an address on the Basic Principles involved in the Treatment of Common Spinal Conditions as well as in the Function of the Viscera. In the short time allowed him he covered all the main features of the subject, including the influence of bodily types on the production of sprains and the significance of anatomical variations in relation to symptoms, these variations being illustrated by radiograms as well as drawings of many anatomical specimens. He also discussed the mechanics of the circulation and respiration, which he illustrated by fluoroscopic tracings of the movements of the diaphragm under different bodily conditions. He pleaded for a thorough examination of the whole patient stripped in cases with symptoms referred to the spine or abdomen, and for thorough X ray examination of the chest, including heart and diaphragm, as well as vertebræ.

On July 5th a discussion on

Reconstructive Surgery in Paralytic Deformities of the Leg

opened with a paper by Dr. MELVIN HENDERSON (Mayo Clinic), which was read in his absence by Dr. BRUCE GILL (Philadelphia). The communication supplied an interesting review of the methods which have been successively used to try to give stability to a lower limb in which paralysis of one or more muscles has upset the normal balance and led to poor function, with or without deformity. Dr. Henderson's figures of the varieties of operation and their results in 105 cases during the four-year period 1924–28 showed that the total percentage of operations was diminishing, as the result of more efficient early treatment, while the proportion of arthrodesis to other methods was steadily rising. [Both these features were noticeable also in most of the other statistics presented.] The essential message of Dr. Melvin Henderson's experience was that if once the delicate muscle balance of the normal lower limb is permanently disturbed, it cannot be restored by any rearrangement of the remaining muscles, nor can gravity be resisted for long by slings of artificial material or even of paralysed tendons; it is necessary to resist the progress of deformity by fusing the three main joints of the tarsus—i.e., the sub-astragaloid, astragalo-scaphoid, and calcaneocuboid—while certain cases demand removal of the whole scaphoid and displacement of the lower part of the foot backward on the astragalus, so as to shorten the part of its axis in front of the leg bones. Most of the subsequent speakers agreed with him that in suitable cases the transplantation of active tendons, or the use of paralysed ones as slings are a valuable supplement to the arthrodesis operation. With judicious selection of cases about 90 per cent. of good functioning feet can be obtained by the method.

Mr. LAMING EVANS (London) gave an interesting review of the progress of surgical treatment of paralyses in the lower limbs. He dwelt at some length on the *management of cases of complete, or almost* complete, paralysis of the quadriceps, stating that a transplanted biceps, an antagonist of the quadriceps during movement, can never be got to extend a flexed knee against gravity, whereas the sartorius, a synergic muscle, can do so. Subsequent speakers pointed out that the object of the transplant was to steady the knee-joint during standing, in which function the quadriceps and hamstrings normally contract simultaneously and, therefore, the transplant might very well restore balance; Dr. Royal Whitman, a staunch advocate of the transplanting operation, finds that it does so in all properly selected cases. All speakers condemned arthrodesis of the knee for a flail knee in childhood, though it was agreed that the operation might have its use for certain adults in special occupations. Mr. Laming Evans also referred to the risks of gangrene and shock in attempts to correct completely by operation severe flexion deformities of the hip and knee; these should be straightened gradually by apparatus after the operation. He found transplantation of the toe extensors into the metatarsal heads for clawing a disappointing operation, as have many other surgeons, and he advised in preference astragalectomy by Whitman's method, which with care and a wise selection of cases he found to give excellent results.—Dr. WHITMAN himself then spoke in support of his operation.—Dr. F. R. OBER (Boston) next emphasised some points which make for success in tendon transplantation operations, and referred to the need for combining them with arthrodesis in many cases.—Dr. L. MAYER (New York) showed an ingenious cardboard model illustrating all the stages of such an operation on a foot.

Dr. LE MESURIER (Toronto) gave some interesting facts about his work with Gallie on tendon-slings, and pointed out that slipping of the tendon is likely to occur if its smooth surface is not scraped away, and that union is best in cancellous bone. He said that the pioneers of the method have now abandoned it for drop-foot and valgus deformities, since the sling is unable to resist gravity, but it is still found useful for some varus conditions, as gravity helps to maintain their correction; it is also useful as a temporary measure in young children, whose bones are not yet developed sufficiently for arthrodesis. Most speakers agreed that the fusion operations gave the best results when done late, though it was mentioned that adults may complain of persistent pain after the operation, whereas this is practically unknown in children.

Dr. WALLACE COLE (St. Paul, Minn.) gave some interesting statistics on a series of 224 foot arthrodesis operations; only two had failed to secure bony union, while only 11 had required further operation; 80 per cent. had given excellent results. He showed clear diagrams of the principles of the chief types of operation in use and in his later cases was tending to favour the three-joint arthrodesis.—Mr. NAUGHTON DUNN (Birmingham), one of the pioneers of this type of operation, pointed out the danger of getting part of the correction of the equinus by downward angulation at the mid-tarsal joint, which gave a persistently painful foot. A number of speakers supported from their experience the practice of stabilising the foot by some type of bone operation before tackling the muscles themselves.

Clinical demonstrations were given at St. Bartholomew's, *Guy's, King's College, and St. Thomas's* Hospitals, and a visit was paid to Alton.

The morning of July 6th was occupied by a series of short papers, each of which represented a great amount of careful clinical work and research.

Disabilities from Low Back Derangement.

Dr. ELLIOTT BRACKETT (Boston) read a paper on the Treatment of Disabilities Resulting from Low Back Derangement, illustrated by lantern slides. Dr. Brackett pleaded for study and treatment of the lower part of the back with its three critical joints of the sacro-iliac and lumbo-sacral junctions *as one mechanism*, because it was impossible for a lesion of any one of the three to occur without altering the strain on the other two. He asked for further study to elucidate the mechanism of the production of pain in the region, which is by no means clear, and pointed out that there are no absolutely characteristic symptoms for each different lesion in this region; pathological conditions may give the same clinical picture as strain. He also asked for a careful study of the systemic condition of each patient and for a critical estimation of the relative importance of various factors in different cases. Among the factors to be weighed were trauma (strain of subluxation); anatomical abnormalities of the spine, such as sacralisation of the fifth lumbar vertebræ, a horizontal position of the sacrum, or abnormalities of the articular facets and of the laminæ and the presence of pathological processes such as tuberculosis or rheumatoid and osteo-arthritis. Finally the lesion in one or all of the three joints had to be localised. As regards anatomical variations Dr. Brackett dismissed sacralisation of the fifth lumbar as of no clinical significance; but he regarded a horizontal position of the sacrum as a factor making for constant, abnormal strain on ligaments and muscles and therefore of serious import. He reminded his audience that normally none of the joints in question allow much movement, but that they act as shock-absorbers. In the normal attitude of good posture, such as Dr. Goldthwait had demonstrated to them two days before, the shocks were reduced to a minimum, whereas alterations in the mechanical balance at once increased the strain on structures, and as soon as it became more than they were designed to meet symptoms arose. It was necessary to find out by careful X ray examination whether anatomical peculiarities were present, then to consider whether they had any effect in increasing the strain on the joints, and finally to treat this region, and indeed the whole body balance, as one mechanism.—Dr. A. **Steindler** (Iowa) emphasised this point.—Dr. T. D. **Adams** (Boston) remarked that the anatomical abnormality had existed from birth, whereas the symptoms came on late, so that they were likely to be due to some superadded pathological condition.—Dr. **Brackett**, in reply, said that he considered that the patient with an abnormal bone condition was likely to be slower in recovering and more subject to relapse, because he started with a smaller margin of safe reserve.

"No Dressing" Treatment.

Dr. **Winnett Orr** (Lincoln, Nebr.) next gave an interesting paper on the details of his "no dressing" treatment of infections of bones and joints. He said that the method was based on the principles originally laid down by the British pioneers, Hunter, Hilton and Lister, whereas modern surgery with its fomentations, irrigations, drainage-tubes, and frequent changes of dressings had got away from Lister's original and valuable technique, as well as from the application of rest which was so necessary to healing tissues. He illustrated his paper by lantern slides of cases showing remarkable results from his method, in a case of neglected osteomyelitis of the upper end of the femur, a compound fracture of the ankle in a very heavy, flabby subject, and two compound fractures of the shaft of the femur, one of which was septic and ununited after it had been plated at another hospital. In all these cases skiagrams were shown demonstrating good bony union and photographs of the patients proved the wounds healed or superficial and the general condition excellent. These and many others had been treated by the method of widely opening all septic cavities, cleaning them out with iodine and alcohol, and packing with gauze saturated in paraffin, which provided at once pressure and drainage; firm dry dressings were then applied without any stitching of the wound, and finally a plaster hip spica in any lesion of the lower limb. If one hip was affected, both were included in the plaster, so as to give absolute fixation of the joints in the affected region. No dressing was done under four weeks and often not till eight weeks, when the plaster and dressing were both changed under anæsthesia in the operating theatre. With this treatment, Dr. Orr said, the temperature falls, pain goes, and toxæmia diminishes within a few days of the initial drainage and splinting. In his view the failures of our present methods of treating acute and chronic bone sepsis are due to: (1) an inadequate primary operation, by which he did not imply that one should open indiscriminately into healthy bone areas when draining osteomyelitis; (2) failure of subsequent immobilisation, both by inadequate splinting and frequent interference; (3) secondary infection during repeated dressings under conditions not providing for absolute asepsis.

Prof. **Hey Groves**, in closing the discussion, said that Dr. Orr's paper would have read like a fairy tale, so revolutionary was his method, but his personality and lantern slides were so convincing that surgeons would feel bound to give his method an extensive trial. He asked the profession to differentiate between the two great groups of cases, which led to chronic bone sepsis—i.e., soiled compound fractures, which it was well known could be disinfected by careful operative technique, and the group of late osteomyelitis, which was septicæmic in character and allowed of no primary sterilisation.

It was evident from Dr. Orr's paper and from the remarks of the surgeons who followed him and have used his method with increasing success, that, as with other innovations which have proved useful, attention to the minutest details is necessary in order to achieve results similar to those of the originator.

An Operation to Check Drop-Foot.

Dr. **Willis Campbell** (Memphis, Tenn.) next gave a cinematographic demonstration of his operation for forming a pyramidal bone spur at the back of the os calcis in order to check drop-foot, and also of patients walking well after the operation. Excellent radiograms were also shown. Dr. Campbell pointed out that most of the cases needed a three-joint arthrodesis of the foot combined with the spur, for which the necessary bone could be got from the slices taken from the tarsal bones. He found the results to be best when the spur was united both to astragalus and os calcis, and when it had a blunt apex which would not fracture.

Mr. R. **Ollerenshaw** (Manchester) showed radiograms of a series of successful cases in which he had employed Dr. Campbell's method.

Dr. **Steindler** next read a paper on the

Compensation Treatment of Scoliosis,

in which he pointed out that the methods used by him were not very different from those formerly used in the so-called corrective treatment. His aims, however, were very different, for it was his object to imitate nature in producing gradually a restoration of the body balance by compensatory curves placed close to the pathological curve, which, though it tended to be reduced by absorption in these secondary curves, could not be abolished entirely in structural cases. Dr. Steindler showed an interesting series of results of treatment in which the severity of the lesion prevented any dramatic cure, but the patients were maintaining their corrected stance over periods of four years and more, with or without a brace. He pointed out that, although the fusion operation might be called for in certain paralytic cases, it should never be performed until the maximum possible compensation had been attained, otherwise the strain on the fused area would be excessive and fracture would occur. Dr. Steindler laid stress on the point that in scoliosis the bone lesion is secondary and the failure of muscle-balance primary, and therefore the aim of treatment should be re-education of muscles under the most favourable conditions—e.g., recumbency or support from a brace. He objected to the traction methods because they gave the muscles no time for compensation. He considered that about 50 per cent. of the cases that came to a surgeon were suitable for this method, which takes about four years for its completion. The unsuitable cases included the very severe paralytic ones and also congenital and rachitic patients.—Dr. **Brackett** drew attention to the importance of educating the patient to know when he is in the correct position, so that instinctive retention of this position might develop.

Pre-hallux as a Cause of Flat-Foot.

The final paper of the session was contributed by Dr. F. C. **Kidner** (Detroit) on the Pre-hallux as a cause of Flat-Foot. He showed skiagrams with this accessory scaphoid present in various stages of development, and described the cases in which flat-foot and an abnormal insertion with loss of power of the tibialis posticus accompanied the bone abnormality. His patients were cured by insertion of the tendon into the under surface of the scaphoid and retention in plaster for six weeks fully inverted.

Dr. D. P. **Willard** (Philadelphia) reported some similar cases.

A RECEPTION AT THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

On the evening of July 4th, a reception was given at the Royal College of Surgeons of England, when the President and Lady Moynihan received a large company of guests in the Museum Hall. Sir Arthur Keith, the Conservator of the Hunterian Museum, then gave a demonstration with the epidiascope of museum specimens illustrating healing and disease in prehistoric times. In a deliberately colloquial manner he spoke of the primitive origins of surgery, pointing out that the oldest known pathological specimen in the world was of an orthopædic nature, inasmuch as the femur of the famous Java man exhibited excellent manifestations of myositis ossificans. But the main part of his amusing address centred round the wonderful specimens of early Egyptian osteology—specimens which were delved from the cemeteries submerged during the construction of the Assouan dam. And here he paid a warm tribute to Prof. Elliot Smith's studies of anthropology, directed alike to Egyptian relics, the art of mummification, and the early history of civilisation.

The introduction of music formed an innovation in College receptions, for in the hall of the College the Marguerite Wortham Orchestra rendered an excellent musical programme. The museum, the conservator's offices, and the Council room were thrown open for the exhibition to the visitors of the Hunterian relics, and recently added preparations of special interest to orthopædic surgeons. The portraits by Reynolds, Lawrence, Romney, Hogarth, and other masters provoked admiration in the Council room, while in the library refreshments were served throughout the evening.

THE DINNER.

The members of the joint meeting dined together at the Café Royal, London, on the evening July 5th, Sir Robert Jones presiding and a very large company being present, including, by special invitation, King Manoel of Portugal.

The Chairman, having given the loyal toasts of His Majesty the King and the President of the United States, called upon Prof. E. W. Hey Groves to propose the toast of the American Orthopædic Association. Prof. Hey Groves first rendered the tribute of British orthopædists to American colleagues for an immense stimulus received in their work from America at the outbreak of the war, a stimulus for which they still had remained grateful. Comparing to-day the orthopædic work in the two countries, in regard to institutions, he said, whether special or attached to general hospitals, one main difference between the countries must be alluded to—apparently in America the workers had no money problems whatever. The need for money being stated it arrived in America, but in this country voluntary institutions have to beg for their bread, while there are other difficulties than pecuniary ones placed in the way of research, for example, the activities of quacks. Of these, the speaker admitted, America also had their quota, indeed such was their supply that they exported them. In conclusion he said that the links of union between America and England forged during the war would hold and the chain would grow stronger. He coupled the toast to which he was speaking especially with the name of the President of the American Orthopædic Association, Dr. Fred Albee, whom he thought of as "a contriver of jig-saw puzzles," but he wished to mention two other prominent orthopædists whose personal connexion with the joint meetings must have impressed everyone, namely, Dr. Royal Whitman, whom he described as "though no longer young in years, yet a storm centre of debate and an admirable examinee," and Dr. J. E. Goldthwait, who was a "wonderful combination of wide knowledge and special technique."

Dr. GOLDTHWAIT interposed here by request and read a telegram which in the early stages of the war had been received in America from the British authorities containing an urgent request for six base hospitals and 20 orthopædic surgeons. The material and the men were immediately dispatched, said Dr. Goldthwait, who pointed out that, while it was a special honour to orthopædic surgery that the first surgical service to be required was orthopædic, the circumstances of the telegram established the American in-comers in an impregnable position from the very beginning, and in that position those 20 orthopædic surgeons, with their entourage, were maintained by two Governments.

Dr. ALBEE, disclaiming any intention of making a long speech, echoed Prof. Hey Groves's words as to the stimulation which the orthopædic surgeons of each country had received from the common direction of their interests and objects. In personal reference to the Chairman he said that 21 years ago he had worked with Sir Robert Jones at Liverpool, and could testify to the wide influence which he had exercised for good over orthopædic surgery throughout the world, and he considered that this influence was much advanced by the able and sympathetic manner in which he had always taught his subject. Dr. Albee closed by alluding to the value of such international meetings as they were now holding, and reflected that the long journeys which had to be undertaken might be of considerable use. Despite the inevitable trials and fatigues of the journey from America to England, he said that the members of the American Association had during its course acquired a valuable knowledge of each other and had thus added to their ability to derive benefit from a confrontation with their British colleagues. He then read the following resolution, which was passed at the Executive Session of the American Association on July 5th:—

> "The American Orthopædic Association, in Executive Session assembled, takes this opportunity of expressing to British Orthopædic Association its appreciation for its gracious hospitality and its lavish expression of good fellowship. Closely bound by every kind of human tie to our British colleagues, we express the hope that this delightful meeting may be the forerunner of other similar happy reunions, and that we may anticipate an early opportunity of greeting our British colleagues in a similar way in the United States. May this resolution serve as the means of carrying a truly fraternal message of gratitude."

Sir ROBERT JONES proposed the health of King Manoel, who was so closely associated with the orthopædic work undertaken during the war at Shepherd's Bush. King Manoel, he said, had not only been a valuable friend from practical and social points of view, but in many ways the idea of curative workshops might be attributed to his invention. He spoke of the cheery and unaffected friendship which King Manoel had displayed while at Shepherd's Bush with the staff, working out the methods of treating the injured and mutilated.

KING MANOEL, in reply, thanked Sir Robert Jones, Dr. Goldthwait and many of his friends in the room, both British and American, for their recollection of the humble worker who during the period of the war tried to do the best that circumstances permitted to him for the mitigation of sufferers. Although, he said, he could no longer be considered to have any direct or practical connexion with orthopædic surgery, the friendly bond between the workers in that specialty and himself would always remain as a recollection and a solace.

Sir ROBERT JONES then proposed the health of the guests, coupling the toast with the name of the Editor of THE LANCET.

Sir SQUIRE SPRIGGE returned thanks briefly, when Dr. GOLDTHWAIT proposed the health of the Chairman in terms of which the audience showed their approval by drinking Sir Robert Jones's health with musical honours.

TUBERCULOSIS ASSOCIATION.

ANNUAL PROVINCIAL MEETING, CAMBRIDGE, JUNE 27TH–29TH.

(Continued from p. 40.)

III. THE CORRELATION OF X RAY FINDINGS IN PULMONARY TUBERCULOSIS WITH THE SYMPTOMS AND PHYSICAL SIGNS.

Dr. J. WATT (Godalming) being in the chair,

Dr. A. E. BARCLAY (Cambridge) dealt with the physical nature of X rays; the causation of the shadows seen in a radiogram of the chest; the voltage, the type of tube, the character of the radiations, and the distance at which a chest radiogram should be taken. Standard conditions, he said, were essential, but most radiologists are troubled by such fundamental things as big variations in town main voltages. Such variations play havoc with standardisation, particularly in the use of hot cathode tubes, where a slight change in the heating filament made so much difference in the quality of the rays. Longer distances were now used in chest work, giving less distortion of the picture and more definition. The best type of film should show no detail in the bones of the thorax. Stereoscopy as a routine measure was not particularly valuable. Screening of the chest before taking a film was invaluable, because it gave information as to the movements of the diaphragm, and to the presence of localised areas of deficient air entry. The shadows at the root of the lung were caused mainly by the blood in the pulmonary vessels. Again, there was not so much air at the roots, and on this account the shadows are denser. Personally he was inclined to lay little or no stress on relatively slight increases in the root shadows, provided that there was nothing else to arouse suspicion. Two points which made him take notice were an area of suspected defective air entry, especially if the root shadow seemed to be particularly enlarged towards this area and secondly, any alteration in the nature of the movements of the diaphragm. These features could only be seen on screen examination. The irregular branched *striæ* spreading out from the root were, in his opinion, due almost entirely to blood-vessels.

It was, of course, in the detection of early pulmonary tuberculosis that X ray examination was of the greatest importance. Advanced disease was usually quite patent clinically, yet frequently more extensive disease was found radiographically than the clinical signs led one to suspect. But, on the other hand, there was a certain percentage of cases in which the radiogram showed no disease when the clinical evidence of its presence was quite strong. The obvious and plausible explanation of the failures in the clinical signs of disease was that the disease was deep-seated, whereas physical examination was more concerned with superficial changes. But why certain cases should fail to give radiographic evidence was not so easy of explanation. Radiographic evidence was naturally confined to macroscopic changes, and if only a few alveoli were affected we were not likely to detect the change. The typical woolly mottling of a tuberculous focus represented not only the disease itself, but a surrounding region filled with the exudate of reaction. He suggested that, in these cases where the radiogram failed to reveal any change, the reaction was deficient. In spite of these exceptions, his faith in the value of an entirely negative X ray examination conducted by a careful radiologist was very high. Radiologists were not justified in calling a shadow tuberculous except on the ground of experience. Exactly the same appearance could be produced by any other low grade localised infection with an inflammatory reaction about it. He held very strongly that the radiographic and clinical examinations should be conducted by different observers. The clinician and the radiologist together would arrive at an opinion that would be neither a clinical nor an X ray diagnosis, but something that really mattered—i.e., *the* diagnosis. It was only by team-work that we could make progress.

Dr. S. VERE PEARSON (Mundesley) said that the subject was a wide one and could not easily be covered briefly. Great advances had been made in recent years but there was still much to learn. He recommended a study of the writings of Wessler and Jaches, Alexander and Beekmann, and the publications of Dr. Kenneth Dunham. He thought there was a tendency to-day to over-emphasise the practical deductions to be drawn from X ray findings in pulmonary tuberculosis. After all the symptoms of a patient were more important than either ordinary physical signs or X ray pictures. It was most important, too, to realise that good and constant standards must be set up in making films of chests, because it was easy, if a radiologist were really clever in altering the circumstances of exposure of a chest, even to produce the picture of a cure attained in a few minutes! He thought this subject of the co-relation of X ray findings with symptoms and physical signs might best be illustrated by him by showing some slides of chests where there was an exceptional correlation one way or the other. It was well known, for example, that severe laryngeal cases and cases complicated by chronic alcoholism often had paucity of ordinary physical signs in the chest, yet X rays revealed extensive disease. He then showed amongst other slides (1) a picture of a very big apical cavity in the case of a man who had been repeatedly examined over many weeks without ever finding any of the ordinary signs of excavation. (2) A couple of slides showing what appeared from X ray examination to be a severe and extensive case compared to one of a much slighter nature; but when the symptoms were compared the former had no fever or other severe symptoms, whereas as in the latter case it was necessary to keep the patient in bed for months and the severity of the illness was great. (3) Two films of the same chest at an interval of nine months looking almost exactly the same, yet from emaciation and feverishness the patient had in the interval progressed to decent body-weight and capability for walking exercise up to ten miles a day. (4) A slide which showed a recent lesion in the left lower lobe producing relapse, which lesion was unsuspected before the X ray film was taken, which saved the patient from having a right-sided artificial pneumothorax attempted, and some other slides where the physical signs were described and were somewhat unusual in their correlation to the X ray appearance or the clinical condition.

Dr. G. T. HEBERT (London) said there could be no two opinions concerning the value of X ray examination to the clinician. Unsatisfactory films, it was true, were unreliable and misleading, but for the purposes of the discussion we must assume that first-class apparatus and technique were used. If X ray findings always agreed with the results of ordinary clinical examination they would be of no service to the clinician. When confronted with a doubtful case of tuberculosis the physician had to make up his mind on four problems—viz., the presence or not of tuberculosis, its extent and character, its activity and the prognosis. In the correlation of X ray findings with physical signs all cases could be divided into four groups: (1) When symptoms and signs were negative and X ray findings negative. This group was usually a large one, and included most of the contact cases. (2) When symptoms and signs were negative and X ray findings positive. If X ray examination was carried out as a routine in this group of cases it would probably be found now and then that one which the clinician would have passed over as non-tuberculous showed a definite radiological lesion. (3) When symptoms and signs were suggestive but the X ray findings positive. Most patients with pulmonary tuberculosis had passed the incipient stage when they first presented themselves. They could be diagnosed with a fair degree of certainty by symptoms, signs, and sputum examination, and for the purposes of diagnosis a radiogram was unnecessary. If sputum examination were negative a positive X ray examination would confirm the diagnosis. (4) When symptoms and signs were suggestive of tuberculosis but the X ray findings negative. It was possible for definite tuberculosis, proved by more than one positive sputum examination, to exist without definite X ray changes, but such instances were very uncommon. Hæmoptysis, pleural effusion, and spontaneous pneumothorax were presumably tuberculous manifestations, but in a considerable percentage of these cases no radiological evidence of disease in the lungs was discoverable. He pointed out that in the non-tuberculous chronic interstitial fibrosis, the abnormal physical signs were usually very marked, whereas the radiogram frequently showed little or nothing wrong. This contrast in the signs and X ray picture he considered to be proof of the non-tuberculous character of the lesion. In tuberculosis the radiogram provided very good evidence of the extent of the lesion. As a rule the disease was more extensive than the physical signs indicated. In regard to activity of the disease, radiological examination was not of much value. It was true that active lesions had certain characteristics, but these were often obscured when active and old foci were intermingled, and on the whole the question of activity was better decided on purely clinical grounds. Concerning the question of prognosis by means of the radiogram, if the condition of the patient was good, he liked to see well-developed mottling. On the other hand, when symptoms, signs, and pyrexia were prominent features but X ray examination showed relatively little, he inferred that the prognosis was bad.

In summing up he made the following points: (1) The clinician would derive most benefit from X ray examination in the province of diagnosis. (2) It was often useful in excluding tuberculosis as well as for confirming clinical evidence which was not quite strong enough to be conclusive. (3) It was essential in cases of initial hæmoptysis, after an idiopathic pleural effusion, or spontaneous pneumothorax, in cases of probable laryngeal tuberculosis, and in some cases of non-pulmonary tuberculosis. (4) It was essential before artificial pneumothorax treatment was commenced and at intervals during the treatment. (5) It often helped in other cases when, for instance, symptoms were severe and the signs slight, or vice versa. (6) It was liable to be misleading when it showed a generalised lesion or indefinite when a homogeneous opacity was present which might be due either to fluid or consolidation. (7) Every clinician should study the X ray films of his cases, because it was only by experience that the significance of X ray findings be discovered and their help utilised to the best advantage.

Discussion.

The CHAIRMAN agreed that while radiograms were useful, they were not infallible. The clinician and the radiologist should work together.

Dr. ERNEST WARD (Paignton) spoke of the variations in the ability of radiologists to take good chest films. He asked what was the significance of pleural rings and cart-wheel shadows.

Dr. GEORGE JESSEL (Lancashire) said it was most valuable to compare X ray findings and physical signs with autopsies, and in this respect the large hospitals had a great advantage over the tuberculosis officer. He thought that diagnosis had not become more accurate in recent years but that there had been a great increase in interest and that treatment on the whole was better. He uttered a warning against depending too much on radiology and neglecting the symptoms and physical signs.

Dr. W. STOBIE (Oxford) was of the opinion that the interpretation of the films should be left to the clinician. Radiograms were part and parcel of our diagnostic equipment, but he thought that all these questions about the correlation of physical signs were highly speculative in the absence of autopsies. He maintained that it was impossible to make a prognosis from a radiogram.

Dr. W. ARNOTT DICKSON, Dr. W. H. DICKINSON, and Dr. F. A. L. HAMMOND also took part.

IV. GAS POISONING AND GUNSHOT WOUNDS OF THE CHEST IN RELATION TO TUBERCULOSIS.

Dr. F. W. BURTON-FANNING (Norwich) *being in the chair*,

Surgeon-Commander A. FAIRLEY (Chemical Warfare Research Department, Porton) spoke on the after-effects of war gassing in relation to the incidence of tuberculosis, on which he said his mind was still open. The clinical side came under the Ministry of Pensions. With much that had been published on the matter in other countries, his department found itself in general agreement. Owing to the fact that warfare gas was a surprise weapon introduced against modern rules of warfare, it had received a vast amount of unfavourable press attention throughout the world. As a result, gas was being blamed for more dire iniquities than had ever before been associated with any war weapon. It was credited for many ailments for which it was in no way responsible. This was borne out by the fact that in the American Army there were only 70,552 gas casualties, but the number of applications for compensation greatly exceeded that number. A Board of American medical officers had examined over two thousand cases claiming disability from gas poisoning. They concluded that gas victims, irrespective of the type of gas used and the severity of attack sustained, showed no marked predisposition to active pulmonary tuberculosis, or to reactivation of a healed or quiescent pulmonary lesion. Further, gas victims presented little evidence of material destruction of lung tissue. French, German, and Swiss authorities had issued reports with similar conclusions.

In the differential diagnosis of pulmonary tuberculosis from the late effects of gas poisoning, Hawes of Boston had stressed that a general appearance of robust health associated with marked symptoms was against tuberculosis, that the lung complications resulting from gas poisoning were usually basal and not apical, and that, following gas poisoning there was apt to be a marked increase in nervous symptoms of every kind. In order to trace any connexion between war gassing and tuberculous or any other disability it was of fundamental importance that the record of war gassing should be unimpeachable.

Dr. G. BASIL PRICE (Ministry of Pensions) dealt with the incidence of pulmonary tuberculosis both after gas poisoning and gunshot wounds of the chest. He was able to show that a marked contrast as to the incidence of tuberculosis existed between the two types of case—viz., that whereas tuberculosis was a rare sequel of gas poisoning, in gunshot wounds of the chest it formed a small but definite percentage which was likely to increase as time went on. During a detailed review of the literature he quoted Sergent's conclusions in 1925 that gassing by itself did not provoke tuberculosis; that where tuberculosis followed gassing, active or latent tuberculosis must have been present; and that if at a later date gassing was followed by tuberculosis, the occurrence was accidental. Dr. Price found in a series of 200 cases in which there had been a definite history of gas poisoning only nine were diagnosed as pulmonary tuberculosis. Of these nine cases in only two was there a probability that the condition was directly caused by the gassing. In a series of 50 cases of wounds of the chest he found pulmonary tuberculosis in 37 of them. The tuberculosis was regarded as a direct sequel of the trauma in 20 cases. He concluded that whereas gassing is unimportant in the later development of pulmonary tuberculosis, in gunshot injuries of the chest (of all types, surface and penetrating), tuberculosis develops later in a small but appreciable percentage. He considered that surface injuries not involving the thoracic cage did not appear to be an ætiological factor in the onset of tuberculosis. When the pulmonary tissue had been definitely injured, and especially when a foreign body was retained in or near the damaged area, activation of tubercle might occur even after a prolonged period.

Discussion.

Dr. A. SANDISON (Ministry of Pensions) said that the mystery of tuberculosis had been increased. The results quoted by Dr. Price were somewhat unexpected, as we now found that it was probably an advantage to have been gassed. The paper showed the value of continuity of records. He supposed that the Ministry of Pensions possessed the most complete health records of a section of the community than had elsewhere been collected. Statistics made from such records were certainly of great value. He pointed out that there was a great increase in the diagnosis of tuberculosis just after the war mainly on account of the possibility of a pension being obtained.

Dr. PEARSON gave some additional details about a case, to which Dr. Price had referred, of œsophageal stricture said to be a sequel to gas poisoning.

Dr. NEVILLE COX (Brighton) asked what proportion of cases with foreign bodies in the lung had received a final award. He thought that it would be of great advantage if these cases could be sent to the tuberculosis officers for purposes of observation.

Dr. JESSEL said that in 1920 he had been asked to work out the connexion between tuberculosis and gas poisoning. In 1281 pulmonary cases he found a small percentage, similar to that stated by Dr. Price, had developed tuberculosis following gas poisoning.

Dr. W. ARNOTT DICKSON (Gloucestershire) said that there now seemed to be three almost sure preventives of tuberculosis—viz., gassing, enlarged tonsils, and delicacy in childhood.

Dr. T. ELLIOTT (Shropshire), after quoting the work of the Henry Phipps' Institute on the question of latent tuberculosis, asked whether or not it was possible that the trauma to the lung opened up a latent lesion instead of causing a fresh onset of the disease.

The CHAIRMAN was interested in the question of laryngitis following gassing, and instanced a case of mustard gas poisoning, followed by aphonia and dyspnœa. A diagnosis of tuberculous laryngitis was made, and the patient was found later to have pulmonary tuberculosis. He gave some figures of patients in Kelling Sanatorium with tuberculosis following gassing and wounds of the chest, and inquired whether it was a fact that the nature of the foreign body played a part in the development of tuberculosis. It was possible that rounded smooth foreign bodies were less harmful than those consisting of roughened angular fragments.

Replies.

Commander FAIRLEY thought that œsophageal stricture was an unlikely sequel to gas poisoning. In experimental work in animals fed on gas-impregnated water no lesion had been found in the œsophagus. A concentration of gas sufficient to cause ulceration of the stomach was quite without effect on the œsophagus. He did not think it was possible to have food impregnated with a concentration of gas sufficient to cause poisoning and in any case it would be extremely unpalatable.

Dr. PRICE said that the men who had received a final award would come to the tuberculosis officer if they became worse. He had found few primary laryngeal complications following gassing, and in any case tuberculous laryngitis was usually associated with advanced pulmonary tuberculosis.

NEW CANCER HOSPITAL FOR MANCHESTER.—It is stated that a new Manchester hospital for the treatment of cancer and for research is to be provided by uniting the Christie (Cancer) Hospital and the Radium Institute on the site of Groombridge House, Withington.

NATIONAL HEALTH INSURANCE.

WORKING OF THE ACTS IN SCOTLAND.

THE tenth annual report of the Scottish Board of Health, which appeared recently,[1] contains a careful study of the working of the National Health Insurance system up to the end of the year 1928, when the Board was superseded by the new Department of Health for Scotland. The summary, which covers a period of ten years, deals with the work of the approved societies, the insurance committees, the Board's inspectors, and the district medical officers, who correspond to the regional medical staff in England and Wales.

APPROVED SOCIETIES.

A reduction in contribution income for 1928 was due to the lowering of the insurable age limit on June 2nd from 70 to 65 years. The state of the several industries is reflected in the sale of insurance stamps, which has dropped in varying degree according to the extent to which their members belonged to the depressed trades. Nevertheless, as in England and Wales, the expenditure on benefits was maintained at a high level. The actual cost of sickness and disablement benefits in Scotland increased from £1,293,000 in 1921 to a peak of £2,021,000 in 1927, falling to £1,750,000 in 1928, when the figure of 1928 would have been still lower had not the disablement benefit kept up, especially in the case of men, the rise in the cost of disablement pointing to an increase either in the number of claimants or in the average duration of the claims. The claims of women are in excess of those of men and there is a movement to separate the two funds for the purposes of valuation.

Elimination of bad claims is the duty of the district medical officers who advise and assist insurance practitioners in counteracting the effect of lax certification, and also help the societies in the selection of cases for reference. As in England and Wales, it has been found that some societies have adopted an arbitrary basis of selection which results in a clogging of the machinery.

The special concession made to genuinely unemployed persons whereby despite their inability to contribute they remain entitled to cash benefits at the minimum rate was continued during the year 1927–28. For this purpose societies received some of the unclaimed money in the stamp sales account and the grants will be more generous in future. In the terms of the amending Act of 1928 such arrears will be entirely excused and will involve no reduction whatever in the cash benefits provided the insured person is able to satisfy his society that he has really been available for employment of an insurable nature, but unable to obtain it. The Ministry of Labour have now arranged to stamp the cards of such persons at the exchanges during each week of unemployment.

Additional Benefits.—The funds allocated to dental benefit were found inadequate to meet the demands, and in many societies the grants had to be reduced from 100 to 75 per cent. of the cost of extractions and conservative treatment, while half the cost of dentures was reimbursed. The amount of money available was further curtailed by the fact that part of the 1928 moneys allocated had been used in the previous year. The amount of money spent on other forms of additional benefit was small. Certain benefits which ceased to operate at the end of the year included medical attendance on dependents and payment of disablement allowance to members not totally incapable of work. Power given by the 1924 Act to expend money on such benefits without approval was repealed in favour of new provisions which enable societies to expend moneys on bona-fide charitable objects, subject to the approval of the Board.

---

[1] H.M. Stat. Office. Cmd. 3304. 6s.

The increased number of references to the district medical officers indicates the increasing popularity of this service. Just as these officers were allowed to advise the societies with regard to the kind of cases to be referred, so they were employed to interview and advise practitioners on the question of certification. An addition to their numbers was under consideration at the end of the year. Of the 38,834 cases referred to them over 22,800 were examined and of these 8487 (or 37 per cent.) were found capable of work. Compared with the experience in England and Wales this seems a high percentage.

Of the total number of references only 1·3 per cent. came from practitioners themselves—regrettable enough although a development in this practice would no doubt require an increase in staff.

INSURANCE COMMITTEES.

The administrative expenditure of these committees was estimated at £49,000. Nine or ten committees required additional credits to balance their accounts. The index registers of the Scottish Committees were cleared in 1926. All known inflation had been removed from them by Oct. 1st, 1927, but effect had still to be given to notifications then being received intimating loss of title to medical benefit at the end of that year. Medical lists were not reduced until the end of 1927.

Special mileage to the amount of £325 was granted to practitioners whose journeys were rendered more difficult by the closing for reconstruction of certain main roads.

During the year 18 complaints were lodged by insured persons or approved societies against insurance practitioners. Six of these involved alleged breaches of the certification rules, four were charges of alleged neglect, seven complaints involved charges of demanding fees from insured persons, and one was a case of an irregularity in causing an insured person to transfer to the practitioner's list. Fines of £5 and £25 were imposed in two cases for irregularities in certification. In a third case in which a lay assistant had been allowed to give certificates the practitioner's list was reduced to 1200. For charging an insured person a fee and raising an action in court to recover it one practitioner was fined £50. For failing to provide proper surgery accommodation fines of £10, £25, and £50 were imposed by insurance committees; in two of the cases the penalty was reconsidered on appeal. Five practitioners were reported by district medical officers for failure to return to them the reports on insured persons referred for *examination*, penalties of £20, £10 and one guinea being imposed. Two practitioners were fined for failing to return medical cards to their committees.

Drug Fund.—Expenditure followed much the same lines as in England and Wales; a peak was reached in 1924, when the amount expended averaged 2*s.* 1*d.* per insured person in the country. The amount has come down steadily since then to reach 1*s.* 10½*d.* last year. A central checking bureau in Glasgow keeps a control on prescribing. In the course of the year panel committees in 10 areas recommended a surcharge in the case of 40 practitioners, and a sum of £267 14*s.* was recovered from them and repaid to the drug fund. In three cases the practitioners appealed, but the committee's findings were upheld. A scheme has been instituted for the testing of drugs and appliances, and insurance committees have been asked to furnish a detailed report of their results.

A sum of £46,000 was allocated to the special mileage and necessitous districts fund, of which £3500 was disbursed centrally for the improvement of the medical service in sparsely populated areas. The remainder went in subsidies to practitioners in isolated single-practice areas for maintenance of telephones, outlying surgeries, provision of ambulance service and grants to attend post-graduate courses.

New regulations were made for exempt persons whereby their title to medical benefit was prolonged. This right is of considerable value because so long as an exempt person remains entitled to medical benefit he is deemed to be insured for widows' and orphans' pensions purposes. An arrangement was made during the year with the Ministry of Labour whereby 1106 claims were referred to the Scottish Board of Health for investigation. Under the provisions of the Unemployed Insurance Act, 1927, it is now possible for a person to claim exemption who is employed in a seasonal occupation which does not ordinarily last for more than 18 weeks in any year, and who is during the rest of the year not ordinarily employed in an insurable occupation. This ground for exemption was a boon to seasonal fishworkers.

Various provisions in the 1928 Act necessitated new regulations. For example, shore fishermen required to be compulsorily insured from Jan. 1st, 1929. A special order was made excluding from insurance those shore fishermen engaged in ventures where the catch is not sold, but is divided among them in kind. The order provided that the cost of contributions payable may be deducted from the gross earnings of the vessel before the share-out among the men takes place. The 1928 Act also made provision for the compulsory insurance of persons who contract to perform work of a manual character for the purpose of the trade or business of another person, and special orders were made to provide for such cases.

During the year 61 employers were prosecuted for non-payment of insurance and pensions contributions. Conviction followed in 40 cases.

INSURANCE INSPECTORS.

Unemployment due to trade depression did not loom so large in Scotland as in other parts of the kingdom. The increase in the insured unemployed was 1·38 per cent. as compared with 5·27 per cent. for the whole of Great Britain and Northern Ireland. The grave unemployment figures in the heavy industries are not due only to the war; the exhaustion of ironstone in Scotland has led to the necessity of importing raw material and the output of the iron and steel industry has been reduced. This reacted on coal mining, and in Lanarkshire during 1928 78 pits employing 3218 men were permanently shut down.

Emigration is responsible for the depletion in the ranks of skilled workmen. From 1921–26 the net emigration from Scotland was 40,852, from England and Wales 59,770; in 1913 the figures were 8188 for Scotland and 27,050 from England and Wales. The figures are serious because they represent the younger and more vigorous workmen. New industries are being developed such as artificial silk, rubber tyre and paper manufacture, but these gains are small in comparison with the losses.

In Scotland the future is likely to impose a rather severe strain upon the insurance scheme in regard to both contribution income and benefit expenditure. Bad trade increases the difficulties in collecting contributions and encourages evasion of payment on the part of employers. On the other hand, the advent of the contributory pensions scheme has effectively increased the employer's interest in and readiness to pay contributions.

The special difficulties of investigation into claims show no sign of diminishing, nor is it proving easier to determine the applicant's age for pension purposes. One man stated that he was 26 when he "first played fitba' for the Hibs"; another remembered that when he was 9 years old he suffered imprisonment for 14 days for stealing apples. But the pensions scheme in conjunction with the Insurance Act has proved a very real boon; even to men in poor-law institutions it has been welcomed as a means of freedom. The substantial benefits of the joint scheme are to-day firmly fixed in the public mind.

DISTRICT MEDICAL OFFICERS.

The experiences of these officers are very similar to those of the regional medical officers in England and Wales. The number of references for women was disproportionate to that for men; 47 per cent. of men referred were found incapable and 53 capable of work, whereas in women referred 32 per cent. were found incapable and 68 capable.

An analysis of 5000 consecutive cases (2378 men and 2622 women) referred in Glasgow was made with a view to determining the female factor. Unemployment figures did not affect the numbers. The cases were grouped in age-periods. In the 16–35 group (by far the largest) married women comprised 46·5 and single women 53·5 per cent. Of the married women 73 and of the single women 71 per cent. were found capable of work. The three outstanding diseases given on the certificate were anæmia, pregnancy, and post-puerperal debility; the percentage found capable of work was 82, 40, and 89 respectively. In the 36–45 group 71 per cent. of the married and 55 per cent. of the single women were found capable.

Bronchitis in this period was one of the main causes of incapacity, but it was evident that the certifying practitioner's opinion was based more on symptoms than on physical signs. The same applies to rheumatism. In the 46–50 group 60 per cent. of the married and 50 per cent. of the single women were found capable. Rheumatism and bronchitis formed 46 per cent. of the references. Of the cases certified as rheumatism 72 per cent. were found capable and again it seems that subjective symptoms were given undue weight. Few cases of cardiac disease were referred; they amounted only to 4 per cent. of the whole and were all found incapable. It was evident that, after middle age at least, the married woman is not a good proposition from the health insurance point of view.

Attention is called in the report to the vague certification used by practitioners. Based as it is on symptoms, it follows inevitably that insured patients are fit for work when they declare themselves to be so and the recipients tend to control expenditure. Accurate certification, it is remarked, must be the foundation on which any medical insurance is based.

An interesting series of investigations was made into cases of anæmia and of albuminuria. In the former it was found advisable to use the Haldane method, 80 per cent. being taken as the standard for men and 75 per cent. for women. On this standard incapacity due to anæmia was present in only 13 per cent. The results suggest the futility of trying to ascertain the presence of anæmia without a hæmoglobin examination.

In the cases of albuminuria the efficiency of the kidney was estimated by the urea-concentration test. In the absence of other abnormal signs, those with a concentration above 2 per cent. were regarded as capable of ordinary work. Œdema and high blood pressure were considered to incapacitate even though the concentration was above this level. Below 2 per cent. most of the cases were regarded as incapable. The test enabled the medical officers to certify 30 per cent. of the cases of albuminuria as fit for work.

The problem of industrial rheumatism is touched on in the report and certain conclusions are reached:

1. That it is advisable to give wide publicity to the necessity for prolonged rest treatment in rheumatic fever.
2. That mitral stenosis should be treated in cardiac wards pending the establishment of compensation.
3. That focal infection should be universally looked for and treated.
4. That the presence of focal infection and age-incidence form a convenient classification for the commencement of preventive measures in cases of industrial rheumatism.
5. That convalescent homes should be not only places for rest, recreation, and general tonic treatment, but should administer the more specific tonic treatment of ultra-violet rays, massage, and radiant heat.

MEDICINE AND THE LAW.

The Croydon Inquests: Action by the High Court.

WHILE the time has not yet arrived for summarising the series of inquests in the Croydon arsenic cases, one step—the quashing of an inquest held on Mr. Edmund Creighton Duff in April of last year and the ordering of a fresh inquest—may be described. If the High Court of Justice interferes with a coroner's jurisdiction, it is usually an indication of some default on the coroner's part. Section 6 of the Coroners Act, 1887, for instance, contemplates that the High Court will order an inquest if a coroner refuses or neglects to hold an inquest which ought to be held. The same Section also authorises the High Court to order a fresh inquest if satisfied that such a course is necessary or desirable, because at the original investigation there was fraud, rejection of evidence, irregularity of proceedings, insufficiency of inquiry, or otherwise. The amending Act of 1926 explained Section 6 as meaning that the High Court could also act whenever satisfied that, in the interests of justice, a fresh inquest was necessary or desirable "by reason of the discovery of new facts or evidence." As is made clear in the latest edition of Jervis on Coroners, the effect of the amendment is that an order by the High Court for a fresh inquest can now be invited by the coroner himself, and is not to be deemed as stigmatising him for some default. The Attorney-General, in asking for a new inquest upon Mr. Duff, was careful to place on record the fact that he was not moving against the wishes of the coroner, but at his request. The verdict on June 1st, 1928, was that Mr. Duff died from natural causes. Dr. Elwell, who attended Mr. Duff, had been puzzled about the cause of death, and had brought the facts to the notice of the coroner, suggesting that the symptoms might indicate some form of ptomaine poisoning. On analysis of certain organs, the public analyst failed to ascertain the presence of poison. In the absence of evidence accounting for the death, Dr. Brontë expressed the view at the inquest that death was due to myocarditis, though puzzled by the vomiting and other symptoms. After the verdict of death from natural causes in June of last year the following facts occurred. Miss Vera Sidney, Mr. Duff's sister-in-law, died in February last, and Mrs. Sidney, her mother, in March. Inquests in both cases produced evidence of arsenical poisoning, and in May Mr. Duff's body was exhumed on Home Office order with resultant indications of traces of arsenic. Without entering into these facts, the Lord Chief Justice said sufficient evidence had come to light since the original inquest to justify the order applied for. The Court, therefore, made absolute a rule for a writ of certiorari for removing the former inquest into the High Court; having by this ancient machinery got the inquest into its own hands, the Court quashed it and ordered a new inquest. Mrs. Duff, the widow, wrote a letter to the press, published in the *Times* of July 2nd, expressing the natural feelings of a wife in regard to the body of her husband not only examined post mortem, but also subsequently exhumed for further examination. She wrote in consequence of reading an announcement that "a second exhumation of Mr. E. C. Duff is being considered"; she protested that the second examination should have been absolutely thorough, and that "it should not be possible in a Christian country that the body of a good and decent citizen should be treated in such a cruel and casual way because two or three Home Office experts disagree, presumably about the decimal quantities of the drugs found in him over a year after his death." "Even savages," she added, "respect their dead." Later in the day on which the letter appeared, Scotland Yard issued a brief official statement that there was no ground for the suggestion that any further exhumation of Mr. Duff's remains would be required by the police. The sympathy, which must always be felt for the relatives during inquiries of this nature, will not be withheld from Mr. Duff's widow. Perhaps the most reassuring feature of the whole story hitherto has been the fact that the action taken by Mr. Duff's medical attendant upon the doubtful symptoms which accompanied the final illness ensured the opportunity for judicial inquiry at the time.

The Prosecution of Col. Kynaston.

The police-court proceedings against Lieut.-Colonel J. W. Kynaston have ended in a victory for him on one point and a defeat (unaccompanied by serious consequences) on another. At the further hearing of the summons against him at Marlborough-street police-court on July 2nd the ground was considerably cleared. The defendant, it will be recalled, is charged with wilfully and falsely pretending to be a doctor of medicine, and wilfully and falsely using the title of "M.R.C.S. Eng." contrary to the Medical Acts. Mr. G. D. Roberts, for the prosecution, explained that he was not saying a word against Col. Kynaston's honour. The prosecution did not impute fraud, and did not ask for a large penalty. The view of the prosecution was that the General Medical Council, as head of the medical profession, was the judge of the standards of professional honour, and had statutory power to strike persons off the Medical Register if certain conduct was found proved. Rightly or wrongly, the General Medical Council, in 1922, found certain conduct by Col. Kynaston proved, and struck him off the Register. The use of the title "doctor," coupled with medical practice, must (said Mr. Roberts) amount to a representation that the defendant was a doctor of medicine. The Royal College of Surgeons had taken away his diploma; consequently Col. Kynaston was not entitled to use the description "M.R.C.S." Col. Kynaston's case, on the other hand, is that his name was illegally removed from the Register for reasons described in THE LANCET lately (June 29th, p. 1370) in connexion with his application for a mandamus. If the law courts will not allow the merits or legality of that removal to be reopened or questioned, then Col. Kynaston maintains that no medical man is obliged to register, that he himself had never claimed to be on the Register, that he has been a doctor for 20 years, and in the common and popular sense of the word he is still a "doctor," no matter though his name has been removed from the Register or though the Royal College of Surgeons has automatically (and, as he maintains, unlawfully) deprived him of his diploma upon such removal. Mr. Cancellor, the magistrate, gave his decision on July 9th. He found—presumably as a question of fact—that the defendant did not wilfully and falsely pretend to be a doctor of medicine; the summons on this point was therefore dismissed. He also found that the defendant did commit a breach of the statute by continuing to use the letters "M.R.C.S."; but he dismissed the summons under the Probation of Offenders Act with a serious caution and warning that persistence in publishing his advertisement would make the defendant liable to serious penalties. The magistrate was for various reasons reluctant to record a conviction against him.

Dr. Bell's Acquittal.

The re-trial of Dr. H. W. Bell, of Oakley-street, Chelsea, on the charge of manslaughter, and of having performed an illegal operation upon Miss Kathleen Kelly, ended on July 2nd, in a verdict of "Not Guilty," on both counts. The previous proceedings, when the jury disagreed, were summarised in THE LANCET of June 15th, p. 1273. In the course of the recent re-hearing before Mr. Justice Swift, at the Central Criminal Court, Sir Henry Curtis Bennett, appearing for the defence, emphasised Dr. Bell's high reputation. Dr. Bell, he said, had merely made an examination of the young woman, which he was perfectly entitled to make, and which was perfectly lawful; he advised that she should go into a nursing home, where she could be properly looked after. Dr. Bell gave evidence after counsel's opening speech for the defence, and the jury returned their verdict of acquittal without leaving the jury box.

IRELAND.

(FROM OUR OWN CORRESPONDENT.)

A PROPOSED MILK BILL.

Dr. E. F. Stephenson, chief medical adviser of the Department of Local Government and Public Health, in a press interview a few days ago, gave information about a milk Bill which the Government intends shortly to introduce. Early last year an inter-departmental committee furnished a report which contained several recommendations for the improvement of the milk-supply of the country. It is on these recommendations that the provisions of the Bill are based. Dr. Stephenson states that the Bill aims at the production of clean milk—not the cleansing of dirty milk—by enforcing strict supervision of the cow, the dairy, and the distribution. To secure these ends a wider interpretation will be given to the words "milk" and "dairy," and the registration of all persons carrying on the trade of dairymen, in addition to the registration of premises, will be made mandatory. It has been shown that clean milk can be produced without any great capital expenditure in altering byres, and that *method*, rather than buildings, determines its hygienic properties. The production of clean milk is not difficult. Dr. Stephenson draws attention to the educative work that has been done by various voluntary organisations, and to the steps that have been taken by his Department to persuade local sanitary authorities to enforce existing laws and regulations. He points out that the Dairies, Cowsheds and Milkshops Order of 1908 is somewhat out of date. The Regulations under the new legislation will not alone deal with the lighting, ventilation, cleansing, drainage, and water-supply of the dairy, but will secure a more thorough supervision, inspection, and examination of dairy cows, the proper grooming of animals, personal cleanliness of milkers and distributors, the cooling of milk, and its conveyance and distribution in sterilised vessels and utensils. Furthermore, the grading of milk and the use of special designations will be authorised, and misleading terms prohibited. The bacteriological examination of milk will be a guarantee to the purchaser of a high quality article, and a protection to the honest vendor against unfair competition. Drastic penalties against selling dirty milk will be enforced. The use of preservatives in milk was prohibited by an Order which came into operation in October last.

Much has already been done, Dr. Stephenson remarks, to prevent the spread of the acute specific fevers through the medium of milk, and the records of the Saorstat compare favourably now with those of other countries as regards milk-borne infection. The Bill now to be introduced enables a medical officer of health to stop the sale of milk if there is epidemiological or other evidence that it is the vehicle of infection. The safeguards relied on in the Bill for the protection of the public against bovine infection are: (1) inspection and examination, (2) tuberculin test, (3) bacteriological examination. The higher grade milk proposed under the Bill must be produced from cows which have passed the tuberculin test and a clinical examination.

He adds that the placing of the Bill amongst the Statutes of the State is a matter of little account in proportion to the spirit with which it is administered. The appointment of a county medical officer of health in every county is essential to attain the objects in view under the present measure. "Success can only be achieved by steady, firm, and uniform administration exercised by a whole-time trained sanitarian. The necessity for these officers is now well recognised, and their appointment is being pressed."

MOUNT VERNON HOSPITAL: STAFF APPOINTMENTS. Mr. Geoffrey Keynes and Mr. Stanford Cade have been appointed surgeons, Lady Barrett and Dr. Malcolm Donaldson gynæcologists to the hospital.

Public Health Services.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

THE following are 1928 statistics of one borough and one urban district:—

Name of district and estimated (R.-G.) population.	Birth-rate.	Death-rates per 1000 of the population.					Death-rates per 1000 births.		
		All causes.	Tuberculosis.	Cancer.	Respiratory diseases with influenza.	*Heart disease.*	Infant and neonatal mortality.	Young child (1–5 yr.) mortality.	Maternal mortality from childbirth.
Ilford .. .. (113,500)	15·8	8·4	0·63	1·26	1·1	1·7	45/24	22	4·0
Edmonton U.D. (73,027)	18·2	9·9	0·87	1·21	1·7	1·4	69/–	37	3·0

Ilford.

Dr. A. H. G. Burton says that the year 1928 was characterised by a heavy incidence of infectious diseases. The attack rate for scarlet fever and diphtheria was the highest for the past five years. There was a small outbreak of paratyphoid fever and small-pox occurred on one occasion. There were 25 cases of paratyphoid, 10 of which occurred in April. The cases continued cropping up at intervals until November. All possible sources of food infection were investigated with no result, and Dr. Burton had no reason to trace the cases to infected cream, which was considered to be the cause of the London epidemic. None of the cases proved fatal. There was one case of small-pox in an unvaccinated girl of 14 and another Ilford resident developed small-pox outside the borough. Both cases were of the mild type and in neither case was the origin discovered. The much-needed cubicle wards at the isolation hospital have been completed. One is a new block consisting of four wards on each side of the duty room with glass partitions and an operating theatre at one end. Another block of obsolete pattern has been converted so as to provide eight cubicles.

The open-air school has been completed and Dr. Burton points out that in the majority of cases new schools cannot be built on open-air lines and that a further advantage of the open-air school is that delicate children unfitted for ordinary school life can be educated together and receive special care, observation, and treatment. Two needs of the school medical service are an increase of the dental staff and the provision of a complete orthopædic scheme. An immunisation scheme against diphtheria has been under consideration and the Ministry have pointed out that such a scheme would not be eligible for a grant under the maternity and child welfare regulations. Scarlet fever has been, on the whole, of a more severe type and has shown a tendency to involve the mastoid bone. Nine per cent. of the cases of scarlet fever developed middle-ear disease and six cases of mastoiditis occurred. In the previous year 5 per cent. of the scarlet fever cases developed middle-ear disease and there was no case of mastoiditis. Antenatal work makes progress. The number of first attendances at the clinics was 198 in 1921 and has gradually increased to 653 in 1928. The number of women admitted to the maternity home has increased from 139 in 1919 to 481 in 1928, and all the patients admitted, who are to be attended by a midwife, are examined at the antenatal clinic.

During 1928 all the new houses built, numbering 877, were private enterprise subsidy houses and the only two notices served for overcrowding were complied with.

Edmonton.

Dr. H. W. Harding says that the housing problem in this urban district is not solved in spite of the efforts of the council. On the one hand are folk living under sordid conditions and quite contented. On the other there are families living under conditions of overcrowding which must sap the vitality of the strongest. Rents are high and so-called furnished rooms are let at an exorbitant figure. The interior of overcrowded houses rapidly becomes dilapidated and the sanitary inspectors have difficulty in deciding as to which defects the owner of the house should be held responsible for. Of the 676 new houses 186 were subsidy houses erected by the local authority and 24 were subsidy houses erected by private enterprise. An unusual occurrence was a plague of flying beetles, which began in one part of the district early in May. The beetles (*Harpalus ruficorius*) swarmed in myriads against the backs of neighbouring houses from fields in which a good crop of potatoes was raised. The trouble lasted about two months and various disinfectants were tried without apparent benefit. On the advice of the Ministry, the farmer planted his land with wheat, which would stand heavy rolling, the idea being to crush any beetles which remained in the ground. Up to April, 1929, there had been no signs of recurrence. It has been suggested that these beetles, which are carnivorous in habit, had made a wholesale migration owing to the exhaustion of their natural food.

The day nursery, which is at present run privately, has been offered to the council and Dr. Harding suggests that a new child welfare centre might be erected on the site, as the present centre is inadequate. Early in 1927 an arrangement was made with the guardians for the treatment of cases of rickets, marasmus, &c., at the North Middlesex Hospital by ultra-violet rays at a charge of 1*s*. per exposure. Dr. Harding complains that out of 128 patients sent to the hospital for this special treatment during 1928, 78 discontinued treatment contrary to medical advice.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED JUNE 29TH, 1929.

Notifications.—The following cases of infectious diseases were notified during the week:—Small-pox, 160 (last week, 166); scarlet fever, 1830; diphtheria, 965; enteric fever, 56; pneumonia, 850; puerperal fever, 37; puerperal pyrexia, 85; cerebro-spinal fever, 12; acute poliomyelitis, 2; encephalitis lethargica, 30; dysentery, 5; ophthalmia neonatorum, 128. No case of cholera, plague, or typhus fever was notified during the week.

The number of cases in the Infectious Hospitals of the Metropolitan Asylums Board on July 2nd–3rd was as follows:—Small-pox, 106 under treatment, 8 under observation (last week 230 and 3 respectively); scarlet fever, 1314; diphtheria, 1635; enteric fever, 10; measles, 211; whooping-cough, 470; puerperal fever, 28 (plus 6 babies); encephalitis lethargica, 124; "other diseases," 35. At St. Margaret's Hospital there were 19 babies with ophthalmia neonatorum.

Deaths.—In the aggregate of great towns, including London, there was no death from small-pox, 2 (1) from enteric fever, 34 (7) from measles, 4 (1) from scarlet fever, 35 (13) from whooping-cough, 21 (3) from diphtheria, 89 (7) from diarrhœa and enteritis under two years, and 27 (2) from influenza. The figures in parentheses are those for London itself.

Liverpool reported 6 deaths from measles; no other great town more than 2. Five deaths from whooping-cough were reported from Leeds and 3 from Birmingham. The highest figures for diarrhœa were 4 deaths each from Liverpool and Manchester, 3 from Birmingham. Four deaths from small-pox are now reported for the month of May from areas outside the great towns. These have been assigned as follows:—2 to Gravesend (Kent), 1 each to Bentley-with-Arksey (Yorks W.R.), and Leigh (Lancs).

The number of stillbirths reported during the week was 294 (corresponding to a rate of 42 per 1000 total births), including 54 in London.

Obituary.

JOHN MITCHELL BRUCE, C.V.O., M.D. LOND., F.R.C.P. LOND., LL.D. ABERD.,

CONSULTING PHYSICIAN, CHARING CROSS AND BROMPTON HOSPITALS.

WE regret to announce the death of Dr. Mitchell Bruce, which occurred at his house in Harley-street on Sunday, July 7th, in the eighty-fourth year of his age.

John Mitchell Bruce was born at Keig, Inverurie, and was educated primarily at the local grammar school, whence he proceeded to the University of Aberdeen, where he graduated M.A. in his twenty-first year. Having decided to study medicine he joined the Middlesex Hospital in 1866 with the intention of graduating in medicine at the University of London. He was a highly successful student both at the hospital and in the examinations for the medical degree of the University, gaining honours, gold medals, and scholarships in several subjects. He graduated in 1870 and proceeded two years later to the M.D. degree, in which year he also obtained the M.R.C.P. Lond. He had in the meantime attended post-graduate classes in special pathology at various centres abroad, especially at Vienna, and on return to England he continued these studies under Burdon-Sanderson and Klein. So that when in 1871 he was appointed lecturer on physiology and pathology at the Charing Cross Hospital medical school, after a brief period as resident at the Aberdeen Royal Infirmary, he was unusually well-equipped for his duties. With Charing Cross Hospital he was connected for over fifty years, for in 1872 he was elected assistant physician; ten years later he became full physician and served with notable success as dean of the medical school; he held his active post until 1904, when he was elected consulting physician. He was for a time physician to the East London Children's Hospital, and for a longer period to the Brompton Hospital for Consumption and Diseases of the Chest, and in the general and the special hospitals he made a distinguished mark as clinician and teacher. His classes at Charing Cross Hospital were held to turn out some of the best trained students in the metropolis, while his demonstrations to the residents at Brompton and to occasional post-graduate workers, especially in the out-patient department, were remarkable for their clearness and practical value.

DR. MITCHELL BRUCE.

In particular reference to his educational work at Charing Cross Hospital one closely associated with the institution writes: "At the close of the last century the medical teaching at Charing Cross Hospital reached a very high level, and was considered equal to the very best in London. This was due to the energy and ability of T. H. Green and John Mitchell Bruce, whose lectures and clinics were attended by a crowd of students from other hospitals. Their teaching was very dissimilar: Green seized on fundamental points and impressed them on the students' minds by constant reiteration; Bruce attracted the student by illustrating his point with vivid descriptions of patients in the hospital. In other respects their methods were different. Green's chief weapon was sarcasm, and after ten minutes' examination many a student has vowed never to enter his ward again, but came again, finding the discipline salutary. Bruce's weapon, on the other hand, was kindness. He seized on the student's trifling knowledge, gave him praise, excused his mistakes, encouraged him to fresh efforts. And this came from Bruce's kindness of heart, which was always evident. To be a student at Charing Cross Hospital was to have Bruce as a friend for life, for his kindness was always manifest. Further he spent infinite pains to give comfort to his patients, while he refused ever to be hurried in the discharge of his duties and would never undertake a consultation unless he was absolutely sure of having time to do his duty by his patient. His name will always be cherished at Charing Cross with deep affection as a wise administrator, a great teacher, and a good friend."

During a large period of his time of office at Charing Cross he lectured upon materia medica and therapeutics and as a result he wrote his well-known work on the subject of which the ten editions have been appearing steadily since 1884, it being stated that 70,000 copies have been sold. Something the same large and merited popularity was achieved by Mitchell Bruce's well-known book on treatment, "The Principles of Treatment and their Applications in Practical Medicine." A treatise of this kind was exactly wanted at the date when it was issued—viz., 1900—for much of the therapeutical teaching in the medical literature of the time was purely symptomatic or empirical, while bedside instruction on treatment was, with notable exceptions, brief, at any rate by comparison with the dissertations on morbid appearances. Mitchell Bruce assumed no therapeutical laws, but tried to find them in the facts of ætiology, pathological anatomy, and clinical characters. These he examined in order to obtain lines of treatment, and the sound logic of the method was immediately recognised by readers whose large number was steadily maintained for subsequent editions.

Dr. Mitchell Bruce had a long and honourable connexion with the Royal College of Physicians of London. He was elected a Fellow in 1878, served on the Council, and became Senior Censor in 1911. This year he delivered the Lumleian Lectures of the College, taking as his subject cardiovascular degeneration. In 1913 he was Harveian orator when in an able dissertation he traced the influence of Harvey's work in the development of our knowledge respecting infection and immunity. The Lectures and the Oration were published in THE LANCET at the date of their delivery. Mitchell Bruce was a past President of the Medical Society of London, and later of the Section of Medicine of the Royal Society of Medicine. He was also at different times editor of the *Practitioner* and co-editor of Quain's "Dictionary of Medicine," where he wrote the sections upon certain forms of heart disease and upon acute and chronic rheumatism. As an editor he brought a clear and well-informed mind to bear upon all his work. It was natural that he should be in request as an examiner, and the universities of Cambridge, London, and Manchester, and the English Conjoint Board all availed themselves of his services in this capacity. Hence at the summit of his career he was an exceedingly busy man, for alongside of his hospital, educational, and literary work he conducted for many years a large consulting practice. The University of Aberdeen made him LL.D., the Royal College of Physicians of Ireland gave him their honorary Fellowship, and in 1919 he was created C.V.O.

Our portrait, by Messrs. Elliot and Fry, depicts him at the age of 60 and at a time when he was an accepted leader of British medicine as a general consultant.

THROMBO-ANGIITIS OBLITERANS.

To the Editor of THE LANCET.

SIR,—In your account of the discussion on Diseases of the Jewish Race at the London Jewish Hospital Medical Society on June 13th (THE LANCET, July 6th, pp. 51, 52), I am reported as saying that in my opinion thrombo-angiitis obliterans was a disease with an economic basis rather than a racial one. May I be allowed to correct this misunderstanding and at the same time to make some remarks on the subject. I certainly did say that some of the Jewish patients had had hardships to pass through in their early life—imperfect nourishment perhaps, qualitatively or quantitatively, in some cases—and that the affected individuals were nearly all of the poorer classes, as were also the subjects of the disease in China and Japan. What, however, I chiefly urged was that there was a constitutional basis of some kind which favoured the development of the disease and which seemed not to be specially connected with the endocrine glands, though it was remarkable, I pointed out, how little evidence there was of any familial incidence.

I would here suggest that the constitutional congenital-developmental factor in question may be of the nature of a primary defect in the walls of the blood-vessels of the limbs, sometimes manifested by definite hypoplasia. Indeed, in cases of intermittent claudication in one or both legs, whether in Hebrew or other individuals of early middle age, a question sometimes arises as to whether the symptoms may not be the result of arterial hypoplasia without any actual thrombo-angiitis obliterans.

The lower limbs may be chiefly affected because, as a rule, they are subjected to more muscular strain than the upper ones; if nicotine is an exciting cause, it should be remembered that more nicotine must pass through the blood-vessels of the parts that are most functionally exercised. The immunity of females may be partly explained by the abuse of nicotine having been as yet very rare amongst Hebrew women of the poorer classes and possibly by there having been less muscular exercise involving the lower limbs. But there may also be some other unknown factor to account for the sex-immunity, which appears to be almost as remarkable as in hæmophilia.—I am, Sir, yours faithfully,

London, W., July 7th, 1929. F. PARKES WEBER.

LOSS OF APPETITE IN CHILDHOOD.

To the Editor of THE LANCET.

SIR,—I was delighted with your annotation (p. 32) under the above heading, and I hope that Dr. Joseph Garland's article may be reprinted in this country in extenso, for it is not easy to get hold of the New England Journal of Medicine. Everything you quote needs saying, and saying vigorously, to every parent troubled with fickleness of their children's appetites. I [illegible]d one thing to the statement, "Where [illegible] rise . . ." [viz., a child's resenting [illegible] breast to bottle, from bottle to [illegible]id, from known to unknown] [illegible]ntial to ensure firmness in [illegible] of mother and nurse, even [illegible] days' misery for all con- [illegible] that the "two or three days' misery" may result in a lifelong dislike of a food and that, necessary as it may be at the time of weaning, it may be avoided later by a little guile and common sense.

Every "modern" baby is brought up to take cod-liver oil and tomato or orange juice, and from nine months sieved greens. The flavours of these can be used to get babies to take pretty well what you will thereafter. Even a bread-and-butter pudding may be "got down," *horribile dictu*, with the help of cod-liver oil. Gradually the flavouring can be cut down, and the child will eat the new food with avidity. A new food and not a new dislike will have been added to the child's repertoire without the two or three days' misery.

I fear that this note may be considered more fitting for a mothercraft journal than the pages of THE LANCET, for the point may appear trivial. But I make it because I have seen little in my study of diet and dietetics which leads me to believe that dietitians realise that our tastes in food may all be acquired tastes and have to be learnt (and taught). Pavlov has shown that even so typical a carnivore as the dog has to be taught to eat meat. Stefánsson had to teach his Eskimo dogs to eat game. Is it too great a jump to assume (when the assumption is backed by observation) that human beings have to learn to eat every new food put before them? "Education" consists in superimposing first of all a conditioned reflex upon an unconditioned reflex, and then conditioned reflex after conditioned reflex upon that. With foods the final stage of education is that a new food should awaken gustatory reflexes and not anorexia.

The practical outcome is: lay your basis of acquired tastes early and anorexia of "unknown origin" is unlikely to trouble you. The theoretical outcome is, alas, a scepticism extending to the whole of modern dietetics.—I am, Sir, yours faithfully,

Potters Bar, July 7th, 1929. V. H. MOTTRAM.

SHEWRY *v.* MAYBURY: A JUROR'S REFLECTIONS.

To the Editor of THE LANCET.

SIR,—I have been sent a marked copy of THE LANCET commenting on the singular trial and verdict which will be known to posterity as Shewry *v.* Maybury. Now that the trial is all over, I should like to call your attention to a letter, which I copy from the *Times* of June 25th, and which, as a juror, I should like to endorse. I imagine it has the assent of most of the other jurors. The letter, which can only be a reference to the case, though it does not allude to it by name, is as follows:—

> *Technical Evidence.*
>
> "As one of the special jurors who have sat during seven days listening to the evidence of a recent trial so fully reported in your columns, may I make a suggestion of public import? Of the handling of the case and the result naturally I say nothing. But if medical cases are brought before juries, is it right that a Judge and a special jury should listen day after day to the evidence of experts and hyper-experts, when much or most of it contradicts the rest? Counsel were labouring among technical terms which they did not always understand or know how to pronounce. Would it not be right one day to elect medical referees, to whom cases of disputed fees or alleged negligence could be brought to be settled in a friendly way if possible or, if brought into court, reduced first to nutshell form by impartial medical referees? "I am, &c.,
>
> "SPECIAL JUROR."

Well, these are my sentiments, and further I can say in regard to your interesting article that I was one of the majority in the jury, who were unwilling that after eight years a case should be brought up against Dr. Maybury. Moreover, in spite of my sympathy for the mother in this case, I now suffer from a distinct feeling that Dr. Maybury did not get justice *on the evidence*. It is an uncomfortable feeling, and I am glad to get it off my conscience. Of the reasons why the jury disagreed I cannot say any-

UNIVERSITY OF LIVERPOOL.—At recent examinations the following candidates were successful:—

M.D.

Helen M. Duvall, W. H. Evans, W. M. Frazer, L. S. Goldman, J. C. McFarland, and F. Murgatroyd.

M.B. AND CH.B. WITH HONOURS.

New Regulations.—Class I.: L. Findlay, T. N. A. Jeffcoate, J. Libman, H. J. Partington. Class II.: D. A. Jones, and J. A. Martinez.

Old Regulations.—Class I.: R. K. Bowes. Class II.: W. W. Gerrard, and J. M. Leggate.

FINAL EXAMINATION FOR M.B. AND CH.B.

Part B. (*New Regulations*)—A. H. Barzilay, M. J. Bennett-Jones, A. T. Halton, J. C. Hill, G. A. C. Lynch, C. L. Pratt, C. K. Sconce, E. B. Whittingham, and J. P. Woodward.

Part III. (*Old Regulations*).—S. Alstead, R. J. Doyle, R. A. Furniss, J. N. Parrington, Muriel S. Roberts, N. W. Roberts, J. L. A. Webster, and J. Williamson.

Part A (*N.R.*)—L. G. Anderson, Marjorie E. Birch, A. Blumfield, C. G. Burgess, G. W. Causey, W. N. Chalmers, J. W. Cheetham, D. H. Collins, A. Curtis, P. P. Fox, D. O. Hughes, V. S. Hughes-Davies, A. T. Jones, R. P. Kemp, F. R. Kitchin, E. W. Malcomson, J. L. Mewton, W. J. Poole, M. Solomon, Honora J. Twomey, T. P. Twomey, and R. Wright.

Part I. (*O.R.*)—E. H. Williams.

Part II. (*O.R.*)—R. G. Walker and E. H. Williams.

DIPLOMA IN PUBLIC HEALTH.

Part I.—R. L. Corlett, R. W. Eldridge, A. B. Follows, Susan H. Gilchrist, and E. Hulme.

Part II.—Kathleen Edgecombe, R. R. Evans, Bridget M. O. Gordon, F. C. S. Hinsbeeck, J. S. Logan, and F. L. Smith.

DIPLOMA IN TROPICAL HYGIENE.

G. D. Drury, N. D. Fraser, J. A. L. Innes, and C. Ramdeholl.

The Ethel Boyce Fellowship in Gynæcology of the University of Liverpool has been awarded to Dr. Gwyneth Griffith; the John W. Garrett International Fellowship in Bacteriology to Dr. Muriel Barton Hall; the Robert Gee Fellowship in Human Anatomy to Dr. R. Doyle; the Holt Fellowship in Physiology to Dr. J. H. Follows; the Johnstone Colonial Fellowship in Biochemistry to Dr. R. W. Brookfield; the Lady Jones Research Fellowship in Orthopædic Surgery to Dr. B. L. McFarland; the John Rankin Fellowship in Anatomy to Dr. J. M. Leggate; and the Thelwall Thomas Fellowship in Surgical Pathology to Dr. E. W. Jones. The Samuels Memorial Scholarships have been awarded as follows: Medicine, Dr. S. P. Meadows; Surgery, Dr. J. C. Ross; Obstetrics and Gynæcology, Dr. M. M. Datnow. The University Graduate Scholar in Medicine is Honora J. Twomey.

THE Parliamentary Secretary to the Ministry of Health, Miss Susan Lawrence, M.P., has appointed Miss Ellen Wilkinson, M.P., to be her Parliamentary Private Secretary.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—The forty-seventh annual dinner of this society was held at the Trocadero Restaurant, London, on July 4th, Dr. Harold Sanguinetti, the President, being in the chair. The toast of "The Society" was proposed in a racy and amusing speech by Mr. Ivor Back, who indicated two kinds of useful meetings for such a society as the West London. One would be a discussion of a common topic about which everyone knew something; the other a discourse from someone who knew everything about an uncommon topic. In his reply, Dr. Sanguinetti related the story of the Society, one of whose aims when founded in 1882, was to promote friendly intercourse and good fellowship among medical men in the area. It was its practice to choose a president in rotation from among surgeons, physicians, and general practitioners, and this year he was occupying the chair as a general practitioner. Their membership, which had reached 650 or more before the war, was still not far short of that number. Even during the war the meetings had been well attended, for their members had been deeply stirred by the marvellous successes of medicine and surgery on the field, and by the problems of maintaining the health of the civilian population at home. Women had since 1924 been admitted into membership. Dr. Julius Burnford proposed "The Guests" in a discourse which traced the origin of hospitality from the time of the cave-man onwards. Sir Nigel Playfair, in reply, admitted that he was the son and grandson of medical men, adding, "I am not quite so lay as I look," and giving a telling example of inherited medical talent. Dr. F. G. Crookshank, speaking as a secretary of 25 years ago, recalled the days when there were giants in the land, and warmly espoused the policy of stimulating the interest of general practitioners in clinical discussions. Dr. F. J. McCann proposed "Kindred Medical Societies," to which Dr. Walter Carr and Dr. Ernest Young replied. "The Chairman" was proposed by Dr. Arthur Saunders, who told how the life of a general practitioner might be combined with a real love of education and a flair for literary effort. During the evening Mr. Herbert Collings entertained the company most entertainingly.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION.—It is hoped that a course in gastroenterology will be held from July 22nd to 26th at the Prince of Wales's Hospital, Tottenham, in conjunction with the North Middlesex Hospital. Those interested are asked to communicate with the Fellowship. From July 29th to August 24th there will be a course in urology at the All Saints' Hospital, Vauxhall Bridge-road, occupying afternoons and evenings. A course in diseases of children will be held at the Queen's Hospital for Children, Bethnal Green, from August 12th to 24th, and an all-day intensive course in medicine and surgery at the Queen Mary's Hospital, Stratford, from August 26th to Sept. 7th. A general course of attendance at the clinical practice of some 40 London hospitals continues throughout the year and may be begun at any time. Details of clinics are provided and the post-graduate is left free to arrange his time-table. Copies of syllabuses and further information may be had from the Secretary of the Fellowship, 1, Wimpole-street, London, W.1.

LONDON HOSPITAL MEDICAL COLLEGE: *Prize-giving.*—Lieut.-Colonel W. M. Pryor, chairman of the College Board, presided on June 28th at the presentation of prizes and certificates to students of the college and dental school by Lord Dawson of Penn, Extra Physician to the hospital. Prof. William Wright, the Dean, said he thought the past year would long be famous in the annals of the hospital and college for the very large number of honours which had fallen to them. In appreciation of services rendered during the King's illness, Lord Dawson had been made a member of the Privy Council, Sir Hugh Rigby had been created a baronet, Dr. Robert Stanton Woods had been knighted, whilst Nurse Black and Nurse Davies had been admitted to Membership of the Order of the British Empire and had been awarded the Royal Red Cross. Among other honours received by active members of the hospital, a knighthood had been conferred on Sir William Paulin, the treasurer, and the Matron, Miss Beatrice Monk, had been created C.B.E. Of former members of the staff of the college, Dr. Chalmers Mitchell, F.R.S., had been knighted; Dr. T. W. Twort had been elected a Fellow of the Royal Society; Prof. J. J. R. Macleod, F.R.S., had been appointed Regius Professor of Physiology at Aberdeen; and Prof. F. Wood-Jones had been invited to occupy the chair of anatomy in the University of Melbourne; whilst Dr. A. W. Woo, a former student, had been elected President of the Chinese Medical Association. Three members of the hospital staff had lately been admitted as Fellows of the Royal College of Physicians, whose Croonian and Goulstonian Lectureships had been offered to two of them, Prof. H. M. Turnbull and Dr. Donald Hunter. Dr. Hunter and Dr. Lewis had been elected to Rockefeller Travelling Fellowships and Dr. L. J. Witts had been appointed Assistant Physician to Guy's Hospital. Of the three distinctions open to undergraduate students of the University of London—namely, the Dunn Exhibition in Anatomy, the Dunn Exhibition in Physiology, and the gold medal for the highest marks in the final examination, the first and last had been gained by London Hospital students—Mr. W. Mushin and Mr. E. A. Hunter. In the first professional examination for the L.D.S., out of 55 separate encounters with the examiners, on no less than 52 occasions were London Hospital students successful. After detailing these and other favourable events, Prof. Wright said he thought this long list of distinctions was unsurpassed in the records of any of the colleges of the University. In conclusion, he referred to the urgent need for improved residential accommodation for students.

Lord Dawson, in presenting the prizes, referred to the work of the Dean—"a man of vision and enthusiasm, and a friend whom no Londoner ever forgets"—and went on to speak of the multiplicity of qualities of head and heart which the medical profession called forth. The unfolding of science and the help it could give to medicine year by year was, he said, illustrated by recent developments with radium, which was going to bring out the necessity for team work. The concluding part of Lord Dawson's speech will be found on p. 85.

The Chairman proposed a vote of thanks, to which Lord Dawson briefly replied.

Freedom Research Entrance Scholarship.—This scholarship in pathology, of the value of £100, tenable at the London Hospital by students of the Universities of Oxford and Cambridge, has been awarded to Mr. J. F. Brock, of University College, Oxford.

DONATIONS AND BEQUESTS.—The late Dr. George Thompson Henderson left £5000 to Guy's Hospital, the income to be used for the general purpose of the hospital other than the medical school.—Mrs. Frances Helen Maria Jacobs, of Fairfield, Lower Shiplake, left £2000 each to the Children's Convalescent Hospital, Beaconsfield, the Medical Auxiliary and Church Society, and the Royal United Beneficent Association, and £1000 to the Wimbledon Hospital.

UNIVERSITY OF ST. ANDREWS.—Mr. Stanley Baldwin will be installed as Chancellor of the University on Nov. 6th and Sir Wilfred Grenfell as Rector on the following day.

DEATHS BY GAS POISONING.—The President of the Board of Trade has appointed a committee to consider the increase during recent years in the number of deaths ascribed to poisoning by coal-gas supplied for domestic purposes, and to make recommendations as to any measures relating to the production and use of gas for domestic purposes which might be taken with a view to diminishing the number of such deaths. The committee consists of Sir Evelyn Cecil (chairman), Sir John Robertson, professor of public health in the University of Birmingham, Mr. R. V. Wheeler, professor of fuel technology in the University of Sheffield, and Mr. F. J. Wrottesley, K.C.; with Mr. H. L. Spencer, of the Board of Trade, Great George-street, Westminster, as secretary.

BROMPTON HOSPITAL FOR CONSUMPTION.—A dinner took place at the Mansion House last week in support of the endeavour to raise £100,000 to provide an adequate annual income for the maintenance of the work of the hospital and money for essential buildings and extensions and the re-equipment of old wards. Lord Reading stated that the hospital has tended a total of 117,000 in-patients and 5,000,000 out-patients.

KING GEORGE'S HOSPITAL, ILFORD.—The Lord Mayor of London has issued an appeal for £50,000, the balance of the amount urgently needed to cover the cost of the first stage of the building operations which have already been begun. The hospital will be a large extension of the existing institution at Ilford with 70 beds; the new scheme provides for 300 beds. Housing schemes have in a short time added 76,000 people to the population of the district.

MEMORIAL TO THE LATE LORD HAMBLEDEN.—Last week the Duke of Connaught unveiled a tablet to the memory of the late Lord Hambleden which has been placed in the entrance-hall of King's College Hospital, of which he was chairman for 20 years. The tablet, which is opposite a memorial to Lord Hambleden's father, the late Rt. Hon. W. H. Smith, whose connexion with the hospital began in 1849, is of granite with a bronze panel bearing an inscription recording his "selfless devotion" to the hospital.

THE REBUILDING OF MIDDLESEX HOSPITAL.—The new west wing is so nearly approaching completion that it is hoped that it will be ready for the reception of patients in October. The building consists of a basement and seven floors. Four of the floors contain 37 beds each and the fifth is a gynæcological unit of 24 beds with its own operating theatre and adjuncts. The walls of the theatre are lined with green-tinted plateglass. The children's ward is on the top floor and has a roof playground. Of the one million pounds which the complete rebuilding will cost over £800,000 has already been obtained.

Medical Diary.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, London, W.

MONDAY, July 15th, to SATURDAY, July 20th.—HOSPITAL FOR DISEASES OF THE SKIN, Blackfriars-road, S.E. Afternoon course in Dermatology. Daily clinical demonstrations. Special demonstrations of interesting cases, Tues. Further particulars from the Secretary.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

MONDAY, July 15th.—2.30 to 5 P.M., Medical, Surgical and Gynæcological Clinics. Operations.

TUESDAY.—2.30 to 5 P.M., Medical, Surgical, Ear, Nose and Throat Clinics. Operations.

WEDNESDAY.—2.30 to 5 P.M., Medical, Skin, and Eye Clinics. Operations.

THURSDAY.—11.30 A.M., Dental Clinics. 2.30 to 5 P.M., Medical, Surgical, Nose, Throat and Ear Clinics. Operations.

FRIDAY.—10.30 A.M., Throat, Nose and Ear Clinics. 2.30 to 5 P.M., Surgical, Medical, and Children's Diseases Clinics. Operations.

UNIVERSITY COLLEGE HOSPITAL, Gower-street, W.C.

TUESDAY, July 16th.—5 P.M., Sir Thomas Lewis, F.R.S.: The Mechanism of Raynaud's Disease (Victor Horsley Memorial Lecture).

ST. PAUL'S HOSPITAL, Endell-street, W.C.

THURSDAY, July 18th.—4.30 P.M., Mr. Frank Kidd: The Overflow Bladder.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

DEBATE ON THE ADDRESS.

ON Friday, July 5th, the debate on the Address thanking His Majesty for the Gracious Speech to the Throne was resumed.

Hygiene on Merchant Ships.

Dr. VERNON DAVIES urged that an Inter-departmental Committee of the Board of Trade and the Ministry of Health should be set up to inquire into the accommodation on ships for seamen and to report to the House as to whether some action could be taken. The situation of the seamen and fishermen in the mercantile marine, he said, was not quite so good as it might be. Their charter, the Merchant Shipping Act, was passed 30 years ago, and since then the only alteration made for the improvement of the conditions of our seamen was made in 1906 when the cubic capacity was increased from 72 to 120 cubic feet. At the present time a space of 72 cubic feet was supposed to be sufficient for lascars, but for the ordinary sailor it was 120. During the war there was an agreement between the controller of shipping and the people interested in shipping with regard to the conditions as to accommodation and standard ships were built in which the conditions were very greatly improved. The seamen even thought that a beginning of new times was at hand. Unfortunately, however, since that time the same rate of progress had not been maintained, but on the contrary there had been some slight set-back. They had to recognise that there were a certain number of ship-owners who did not give that care and attention to the conditions of their men that they should, and, as in all legislation, it was necessary to legislate for the recalcitrant and the backward. The "Regulations and Instructions for the Survey of Ships" issued by the Board of Trade, which was the guiding principle, had the fault that it simply made suggestions and was not compulsory. In Australia and also in Norway there were Acts of Parliament which made these things compulsory and by that means alone they were gradually but surely stealing ahead of this country in the accommodation provided for their seamen. In Australia there were medical men whose duty it was to supervise the hygienic accommodation in ships. There was nothing of the kind in this country, except in the Royal Navy, where on the staff of the Director-General of Medical Services there was an officer whose duty it was to see that in our warships there were proper hygienic conditions for the men. A recently inspected 1928 vessel, quite good in ordinary equipment, housed sailors and firemen in the forecastle and had only one wash-basin and shower-bath for all the sailors and firemen—20 in number. Another up-to-date vessel provided the sailors with a mess-room in addition to the sleeping room, but both were in the forecastle. Again a vessel with a large crew and a doctor had no hospital. It was a remarkable thing that it was not compulsory to provide a hospital on these ships. Another thing which would astonish the House was that it was not necessary to provide sanitary accommodation on a ship unless the owner wished to count that space for a reduction of dues for tonnage. Parliament had done something for the slums on shore, but it never seemed to enter their heads that these men who brought food to this country should be provided with proper hygienic and sanitary accommodation.

HOUSE OF COMMONS.

THURSDAY, JULY 4TH.

Police Called into Antivivisection Meeting.

Mr. DAY asked the Home Secretary whether his attention had been drawn to the recent disturbances at a meeting of the British Union for the Abolition of Vivisection at Caxton Hall, Westminster; if any request was made to the Metropolitan police authorities to provide adequate police protection on this occasion; and how many were specially detailed for this duty.—Mr. CLYNES replied: Yes, Sir. In response to the original request for police assistance, 12 police were sent and, subsequently, on receipt of a further message, 17 more.

Mr. BOYCE asked the Home Secretary whether he had received representations in regard to the disturbances at the meeting referred to above, and the alleged refusal of the police officers present to turn out the organised disturbers of the meeting unless the entire hall were emptied; whether any instructions were given to the police officers in question by his department; and if he would consider taking some steps whereby public meetings called for lawful purposes should receive the necessary police protection to carry out the purposes for which such meetings were convened.—Mr. CLYNES replied: The whole incident is under investigation by the Commissioner of Police, and I should prefer to have his report before saying anything further about it. If the hon. Member will repeat his question in a week's time I hope I may then be in a position to reply more fully.

Registrars and Vaccination Exemptions.

Mr. JAMES GARDNER asked the Minister of Health whether he was aware that some of the registrars of births and deaths were refusing to accept statutory declarations from mothers claiming exemption from the vaccination of their children; and if he would take steps to place the mother in the same position as the father for the purpose of the Vaccination Acts.—Mr. GREENWOOD replied: Registrars of births and deaths do not deal with statutory declarations of conscientious objection to vaccination, this being the duty of the vaccination officers appointed under the Vaccination Acts. I am advised that the obligation to cause a child to be vaccinated is placed on the person having the custody of the child, and, consequently, a declaration made by the mother, under the Vaccination Act, 1907, would not exempt the father from liability if he has the legal custody of the child. As regards the last part of the question, any such action would require fresh legislation, which I could not at present undertake to introduce.

Refuse Nuisance at Iver, Buckinghamshire.

Sir ALFRED KNOX asked the Minister of Health whether his attention had been drawn to constant complaints from the Iver district of Buckinghamshire regarding the dumping of London refuse at Iver and Little Britain, in Middlesex; that Mr. Daws, the public cleansing inspector of his department, reported last March that he had found these complaints on local investigation to be well founded; and whether he would see his way to take action to mitigate the nuisance from smoke, smells, flies, and rats, pending the report of the departmental committee recently appointed to recommend permanent measures.—Mr. GREENWOOD replied: I am aware of these complaints. I understand that in one case, where the district council have adopted special by-laws, conditions have improved. In the other case, the local authority have not adopted similar by-laws. I have no legal power myself to deal with particular cases of this kind; but where there is a nuisance or danger to health the local authority can move. The general problem is now being considered by the committee to which the hon. Member refers, and any comprehensive measure must await their report.

Grading of Milk.

Brigadier-General CLIFTON BROWN asked the Minister of Health whether, in view of the frequent misleading of the public by the present system of grading milk as I. Certified, II. Grade A (tuberculin tested), III. Grade A, and IV. Pasteurised, he would alter these designations to Grades A, B, C, and D, so that the purchaser might more easily recognise which was the highest grade of milk.—Mr. GREENWOOD replied: I will bear the hon. Member's suggestion in mind, but to give effect to it would involve the introduction of legislation which I cannot contemplate during the present session.

Panel Patients in Great Britain.

Mr. DAY asked the Minister of Health the number of panel patients at the present time in Great Britain, and the number of doctors who had been removed from the panel; and if he could give particulars.—Mr. GREENWOOD replied: The number of insured persons entitled to medical benefit in 1928 was about 14,800,000; 46 insurance practitioners have been removed from the medical list since 1913, when medical benefit came into operation. The figures relate to England and Wales. Questions relating to Scotland should be addressed to the Secretary of State for Scotland.

Deaths after Vaccination.

Mr. NEIL MACLEAN asked the Minister of Health whether his attention had been called to the coroners' inquests on deaths following upon vaccination; whether he was aware that since July, 1928, there had been 65 cases of serious illness following vaccination, 32 of which proved fatal; and whether he would consider the setting up of a committee of inquiry to go into the whole question of vaccination, and have among the personnel of any such committee representatives of the public.—Mr. GREENWOOD replied: The answer to the first part of the question is in the affirmative. As regards the second part, 27 cases (and not 65) in which symptoms suggestive of disease of the central nervous system following within a month of vaccination were reported to have occurred during the period from July 1st, 1928, to June 30th, 1929. Of these cases 13 were fatal. As regards the third part, the whole question of vaccination has been recently examined by an expert committee, a report by whom was published last year and is now receiving my careful consideration. Investigations are still being made into certain questions by this committee, and I do not consider that any useful purpose would be served by the appointment at the present time of a further committee of inquiry.

Small-pox in West Ham.

Mr. GROVES asked the Minister of Health the total number of cases of small-pox in the West Ham county area since January, 1929; whether the disease had been of a mild character; and what fees had been paid to the public vaccinators for their services from January, 1929, to the end of May.—Mr. GREENWOOD replied: 690 cases of small-pox were notified in the county borough of West Ham during the 26 weeks ended June 29th last. These figures are provisional. The disease has, generally, been of a mild degree. The amount of the fees paid to the public vaccinators in respect of the vaccination of persons resident in the county borough during the three months ended March 31st last was approximately £91. Information as to the fees paid in respect of the months of April and May is not yet available.

Ratification of Washington Convention.

Sir ASSHETON POWNALL asked the Minister of Labour the terms of the announcement made at Geneva with regard to the ratification of the Washington Convention, and to give details of the precise nature of the obligations which they had entered into.—Miss BONDFIELD replied: The statement made by the British Government representative at the recent International Labour Conference was in the following terms: "I am authorised to state that His Majesty's Government in Great Britain propose to take the necessary steps to ensure at the earliest possible moment the ratification of the Washington Hours Convention. That statement requires no further explanation and would only suffer at this moment by further elaboration. I should, however, add that I understand that in introducing the hours legislation necessary His Majesty's Government will take account both of the Washington Convention and the London Agreement." I have nothing at present to add to that statement.

MONDAY, JULY 8TH.

Vivisection of Dogs.

Sir ROBERT GOWER asked the Home Secretary whether it was his intention to introduce legislation prohibiting the vivisection of dogs.—Mr. CLYNES replied: This is a matter on which the Government must be guided by the best possible advice which it can command, and having regard particularly to the carefully considered opinion on the subject which was expressed in the memorandum of the Medical Research Council presented to Parliament in 1927. I am afraid that I cannot undertake to introduce legislation on this subject.

Post-Vaccinal Encephalitis.

Mr. GROVES asked the Minister of Health how many certificates had been received in which the words vaccination or vaccinia or post-vaccinal encephalitis occurred as the cause of death since Jan. 1st this year; in how many other cases did death occur within one month after vaccination; the ages of the persons to whom both sets of death certificates referred; and in which cases were inquests held.—Mr. GREENWOOD replied: Since Jan. 1st, 1929, ten death certificates have been received in which the words "vaccination," "vaccinia," or "post-vaccinal encephalitis" appeared in the coroner's certificate or the medical certificate of the cause of death. The ages of the deceased were respectively 4 weeks, 4 months, 5 months, 6 months, 8 years, 9 years, 10 years, 17 years, 26 years, and 31 years; inquests were held on the persons aged 8 years, 10 years, 17 years, 26 years, and 31 years respectively. In addition I have information of seven cases in which death occurred within one month after vaccination. The ages of the deceased were respectively 9 years, 10 years, two of 13 years, 14 years, 51 years, and 58 years; inquests were held on the persons aged 10 years, 14 years, 58 years, and on one of the persons aged 13 years.

Medical Research in India.

Major GRAHAM POLE asked the Secretary of State for India whether he would inform the House as to why the Report of the Committee on the Organisation of Medical Research in India has not been published; whether he was aware that the All-India Medical Congress had urged its publication; whether any protests had been received against the proposed location of the Central Medical Research Institute at Dhera Dun; and if the legislative assembly would be consulted before any decision was taken.—Mr. WEDGWOOD BENN replied: I am informed that this report was published about five weeks ago. Some protests were made against the location of the Central Medical Institute at Dehra Dun; but the expenses for the scheme as proposed were approved on Jan. 29th by the Standing Finance Committee of the Legislative Assembly.

Veterinary Training in London.

Lieut.-Colonel Fremantle asked the Minister of Agriculture whether he had yet received the Report of the Committee appointed to consider the existing facilities for training veterinarians in London; whether this report would be published as a Parliamentary Paper; and, if so, when.—Mr. Buxton replied: No, sir; but I understand that the Committee has reached the stage of considering a draft report. When the report is received it will be printed and published, and copies will be available for the use of members.

Health of Miners in Rhodesia.

Lieut.-Colonel Fremantle asked the Under Secretary of State for the Colonies, whether the governor of Northern Rhodesia had been asked to submit proposals for the removal of the capital of that territory from Livingstone; whether, in view of the new mining developments in the copper field in that country, any special arrangements were contemplated in regard to the recruitment, supervision, health, and education of natives employed in connexion with the copper mines; and whether these matters would be under the direct control of the government or left to the mining companies.—Mr. Ponsonby replied:—The reply to the first part of the question is in the affirmative. Education is controlled directly by the Government; recruitment, housing, and health are controlled by the mining companies under Government regulation and inspection. The Government already has ample powers in connexion with these matters, but the Secretary of State is not satisfied with the information which he has received with regard to the health of the miners and he has called on the governor for further report and recommendations. Special arrangements for education of the natives at these mining centres are under the consideration of the Advisory Committee on Education in the Colonies. I may add that a revised mining Law is in course of preparation.

Veterinary Services in the Colonies.

Lieut.-Colonel Fremantle asked the Under Secretary of State for the Colonies what action was being taken to give effect to the recommendations of Lord Lovat's Committee on the development of veterinary services in the Colonial Empire, and, in particular, whether the scholarship scheme for recruiting and training veterinary officers for Colonial governments was being proceeded with; and whether it would come into operation this year.—Mr. Ponsonby replied: A despatch was addressed to Colonial Governments in April last dealing with the recommendations of this Committee and asking for their observations upon them. Replies to this despatch are now being received. In view of the present lack of qualified candidates the Secretary of State is of opinion that the first step towards the further development of the Colonial Veterinary Services should be the institution of the scholarship scheme which the Committee recommended, but he fears that it will not be possible to bring this scheme into operation this year.

Hydro-Therapeutic Treatment for Insured Persons.

Dr. Morris-Jones asked the Minister of Health whether he was aware that a scheme had been submitted by the British Spa Federation to provide hydro-therapeutic treatment for insured persons suffering from chronic rheumatism as an additional benefit under the National Health Insurance Act; and whether such scheme had received the sanction of the Ministry.—Miss Susan Lawrence (Parliamentary Secretary to the Ministry of Health) replied: The answer to the first part of the question is in the affirmative. The proposed scheme has received careful consideration, but has not yet been sanctioned. The present list of additional benefits already affords to approved societies a wide variety of forms of remedial treatment from amongst which they may select those to which the limited funds available for the purpose out of their disposable surpluses shall be allocated, and before adding further benefits to that list my right hon. friend would require to be satisfied that there was a fairly widespread desire on the part of societies for such an extension.

Salary of a School Dentist.

Mr. Thorne asked the President of the Board of Education whether his attention had been called to an advertisement inviting applications for appointment as a school dentist to the West Ham education committee at a salary of £450 a year, rising by annual increments of £25 to £500; that the advertisement had been declined by three professional publications on the ground of the salary being below scale; and whether the proposed salary was authorised by his department.—Sir C. Trevelyan replied: I am aware that the West Ham Education Committee propose to appoint an additional school dentist, but the circumstances referred to by the hon. member have not previously been brought to my notice. The Board have not prescribed or authorised the salary of this or any other school dentist.

TUESDAY, JULY 9TH.

Adoption of Children in Scotland.

Sir George Penny asked the Secretary of State for Scotland whether an Adoption of Children (Scotland) Bill would be introduced on the lines of the English Adoption of Children Act.—Mr. Adamson replied: The question is receiving consideration, but I am unable at present to give any undertaking as to legislation.

War Pensions Administration.

Mr. Kingsley Griffith asked the Prime Minister whether it was proposed to obtain powers to remove the pension grievances of ex-Service men and their dependants as specified in the proposals of the British Legion, and in particular with regard to the operation of the seven-year limit.—Mr. F. O. Roberts (Minister of Pensions) replied: Representatives of the British Legion have submitted certain proposals to me on various matters connected with the administration of war pensions, and these are having my immediate consideration. The point mentioned in the questions is certainly to be dealt with, but I cannot at this early date announce any definite decision. In the meantime I may say that the necessary steps are being taken to ensure that no case shall be rejected merely on the ground that it is submitted beyond the time-limit.

Protection against Air Gas Attack.

Brigadier-General Clifton Brown asked the Prime Minister whether the committee which has been considering plans for the protection of the civil population from attack from the air by poison gas had yet evolved a scheme, and, if so, whether the British Red Cross and local authorities were taking steps to operate it in case of necessity.—Mr. Ramsay MacDonald replied: In view of the recent ratification of the Geneva Gas Protocol of 1925 by most of the important European States, including this country, I do not think this is a moment to press the local authorities to develop plans for the protection of the civil population against gas attack. Much preparatory work had, however, been done by the Committee of Imperial Defence upon this problem prior to the ratification of the Protocol, and that work will not be thrown away if, unfortunately, a situation should hereafter arise requiring as a measure of prudence the development of plans for this purpose.

Children in Slum Areas.

Mr. Simon asked the Minister of Health whether he was aware that there were actually more children living in slums to-day than ten years ago, and whether he was prepared to enable their parents to move them into decent houses by some form of children's rent allowance.—Mr. Greenwood replied: I am aware of the unsatisfactory conditions under which many families are living. The provision of better accommodation for such families is one aspect of the general problem of the slums which is engaging my attention; but the hon. Member must not assume that I accept his view that the adoption of a system of children's rent allowances is a solution of this problem.

League of Nations and Radium Supplies.

Commander Bellairs asked the Minister of Health what steps had been taken in regard to international action as to the supply and price of radium; and whether the report of the Radium Subcommittee of the Committee of Civil Research had been brought to the notice of the League of Nations.—Mr. Greenwood replied: The report of the Radium Subcommittee has been brought to the notice of the League of Nations Health Organisation. As regards the supply and price of radium there is for the time being nothing to add to the reply given on April 18th.

Food Value of Half-Meat Cheese.

Mr. Remer asked the Minister of Agriculture if his attention had been called to the importation of large quantities of cheese from Holland and elsewhere which was sold at low prices as cheese, but which was known in the trade as half-meat cheese, and, in view of the low food value of this cheese, if he would take steps to see that this cheese was labelled half-meat cheese.—Mr. Addison (Parliamentary Secretary to the Ministry of Agriculture) replied: The question of the sale of both home-made and imported half-meat cheese has been constantly before the Ministry for some time past. Local authorities under the Food and Drugs (Adulteration) Act, 1928, have power to deal with cases where it is sold under a name which indicates that it is whole-milk cheese, and convictions have been obtained from time to time. In the opinion of my right hon. friend the fresh legislation which the hon. Member's proposal would involve could not at present be justified.

Scottish Local Authorities and Local Government Act.

Mr. DUNCAN MILLAR asked the Secretary of State for Scotland the number of resolutions he had received from town councils, education authorities, parish councils, and other public bodies in Scotland, respectively, calling for the suspension of the operation of the Local Government (Scotland) Act, 1929, until it had formed the subject of further inquiry or for the amendment of the provisions of the Act.—Mr. ADAMSON replied: The numbers are as follows: town councils, 23; education authorities, 7; parish councils, 59; other public bodies (including the *Association of Education Authorities*), 2.

Appointments.

WOOD, E. A., M.B., B.S. Lond., has been appointed House Surgeon to the Swindon Victoria Hospital.

Certifying Surgeons under the Factory and Workshop Acts: HAMILTON, A. B., M.B., Ch.B. Glasg., D.P.H. (Tipton District of Stafford); HUTCHISON, T. P., M.B., Ch.B. Glasg. (Muirkirk District of Ayr); and MORTIS, R. H., L.R.C.P. Lond., M.R.C.S. (Hertford).

City of London Maternity Hospital: ALLAN, W.B., M.B., B.S. Durh., Senior Resident Medical Officer; TAIT, C. B. V., L.R.C.P. Lond., M.R.C.S., Junior Resident Medical Officer.

Glasgow Royal Maternity and Women's Hospital: CROCKETT, MARGARET G., M.B., Ch.B. Glasg., and FULTON, J. B., M.B., Ch.B. Glasg., Indoor House Surgeons; SIMPSON, J. R., M.B., Ch.B. Glasg., and BARROWMAN, JEAN M., M.B., Ch.B., Outdoor House Surgeons.

Vacancies.

For further information refer to the advertisement columns.

Ashton-under-Lyne District Infirmary.—Asst. Radiologist. £500.
Bethnal Green Hospital, E.—Asst. M.O. £350.
Birmingham and Midland Homœopathic Hospital and Dispensary, Easy-row.—H.S. £150.
Birmingham City Mental Deficiency Institution, Coleshill Hall.—Med. Supt. £700.
Birmingham General Hospital.—Res. Surg. Reg. £100–£140.
Birmingham University.—Walter Myers Travelling Studentship £300. Also Lecturer in Physiological Dept. £400.
Bolton County Borough Education Committee.—Asst. School M.O. £600.
Bootle Borough Hospital, Derby-road.—Sen. M.O. Also Two Jun. M.O.'s. At rate of £130 and £125 respectively.
Bournemouth, Royal Victoria and West Hants Hospital.—H.S. At rate of £120.
Bradford Royal Infirmary.—Two H.S.'s. Each £150.
Brighton, Royal Sussex County Hospital.—H.S. £150.
Bristol General Hospital.—H.P.'s and H.S.'s. Also Obstetric Officer. Each at rate of £60. Also Cas. H.S. At rate of £80.
Bristol Royal Infirmary.—Sen. Res. M.O. £200. Also Res. HS.'s. to Special Departments. At rate of £60. Res. Cas. H.S. and Dental H.S. At rate of £80 each.
British Red Cross Society's Clinic for Treatment of Rheumatic Diseases, Park Square East, Regent's Park.—Med. Supt. £600.
Burton-on-Trent General Infirmary.—Second Res. H.S. £150.
Cairo, Egyptian University.—Prof. of Clinical Pathology. £E.1500.
Cardiff Royal Infirmary.—H.S.'s and H.P.'s to Special Depts. Each at rate of £50.
Chester Royal Infirmary.—H.S. and Cas. O. £120.
Derby, Derbyshire Hospital for Women.—Hon. Asst. S. Also H.S. At rate of £150.
Dorset County Council.—Asst. School Dentist. £450.
Dreadnought Hospital, Greenwich.—Asst. Radiologist. 50 gns.
Dundee Royal Infirmary.—Visiting M.O.
Eastbourne, Princess Alice Memorial Hospital.—Jun. H.S. At rate of £100.
Evelina Hospital for Children, Southwark, S.E.—H.S. At rate of £120.
Exeter, Royal Devon and Exeter Hospital.—Asst. H.S. At rate of £100.
Exminster, Devon Mental Hospital.—Jun. Asst. M.O. £300.
Gloucester, Gloucestershire Royal Infirmary, &c.—Second H.S. At rate of £100.
Great Yarmouth General Hospital.—Jun. H.S. £100.
Greenwich Union.—Fifth and Sixth Asst. M.O.'s. Each £300.
Guy's Hospital, Venereal Diseases Clinic, S.E.—Three M.O.'s. Each £365.
Holborn and Finsbury Hospital, Archway-road, N.—First Asst. M.O. £500.
Hull Maternity Home and Infants' Hospital, Hedon-road.—Res. M.O. £450.
Ilford Emergency Hospital.—H.S.'s.
Invalid and Crippled Children's Society's Hospital, Balaam-street, Plaistow, E.—H.S. to Ear, Nose and Throat Dept.
Liverpool, David Lewis Northern Hospital.—Med. Tutor and Registrar. £120. H.P.'s and H.S.'s. Also Hon. Anæsthetists.
London Jewish Hospital, Stepney Green, E.—Hon. M.O. for Actino-Therapeutic Dept. Also Out-Patient Asst. At rate of £50.
Lowestoft and North Suffolk Hospital.—H.S. £120.
Maidstone, West Kent General Hospital.—Hon. Anæsthetist.
Malayan Medical Service.—Asst. Med. Supts. for Mental Hospitals at Singapore and Tanjong Rambutan. Each £700.
Manchester City.—Asst. Tuberculosis Officer. £650.
Marseilles, Queen Alexandra Memorial Hospital.—Res. M.O. At rate of £150.
Middlesex Hospital.—Asst. to Ophthalmic Dept. £100.
Newcastle-upon-Tyne, Education Committee.—Asst. S.M.O. £650.
Nottingham General Hospital.—Two H.S.'s for Special Depts. Each at rate of £150.
Oldham, Royal Infirmary.—H.P.'s and H.S.'s to Special Depts. Each at rate of £175.
Oswestry, Shropshire Orthopædic Hospital.—H.S. £200.
Plaistow Fever Hospital, E.—Second Asst. M.O. £300.
Preston and County of Lancaster Queen Victoria Royal Infirmary. H.P. Also H.S. Each at rate of £150.
Prince of Wales's General Hospital, Tottenham, N.—Hon. Asst. P.
Princess Louise Kensington Hospital for Children, North Kensington.—Hon. Radiologist.
Rochester, St. Bartholomew's Hospital.—H.P. At rate of £175.
Rotherham Hospital.—Sen. H.S. £200.
Royal Army Medical Corps.—25 Commissions.
Royal London Ophthalmic Hospital, City-road, E.C.—Gifford Edmond's Prize in Ophthalmology. £100.
Royal Waterloo Hospital for Children and Women, Waterloo-road, S.E.—Cas. O. £150.
St. Albans, Napsbury Mental Hospital.—Jun. Asst. M.O. £485.
St. Andrew's Hospital, Devons-road, Bow, E.—Three Asst. M.O.'s. Each £350.
St. Mary's Hospital for Women and Children, Plaistow, E.—Res. and Asst. Res. M.O.'s. At rate of £175 and £120 respectively.
St. Thomas's Hospital.—Three Med. Regs. Each £250.
South Africa, Bloemfontein Hospital.—Sister for X Ray and Electrical Dept. £300.
Stoke-on-Trent, North Staffordshire Royal Infirmary.—H.S. £150 Also H.S. to Ophthalmic and Aural Depts. At rate of £150
Swansea Hospital.—Cas. O. £150.
Torquay, Torbay Hospital.—Hon. Surgeon to Surgical Out-patients.
University College Hospital.—First Hon. Asst. to Ear, Nose and Throat Dept.
West End Hospital for Nervous Diseases, Gloucester Gate, Regent's Park, N.W.—Jun. H.P. At rate of £100.
West London Hospital, Hammersmith, W.—Aural and Ophth. H.S. and Res. Asst. Cas. O. At rate of £100. Also Res. Anæs. At rate of £100.
Willesden General Hospital, N.W.—Clin. Assts. to Special Depts.
Windsor, King Edward VII. Hospital.—Third H.S. At rate of £100.
Wolverhampton Royal Hospital.—Hon. Surgeons to Ear, Throat and Nose Dept.
Woolwich and District War Memorial Hospital, Shooters-hill, S.E. H.P. and H.S. Each at rate of £125.
Worcester County and City Mental Hospital, Powick.—Jun. Asst. M.O. £350.
Wrexham and East Denbighshire War Memorial Hospital.—Res. H.S. At rate of £160.

Births, Marriages, and Deaths.

BIRTHS.

DYKE.—On July 8th, at a nursing home, to Janet, wife of Dr. S. C. Dyke, of 9, George-street, Wolverhampton—a son.

HANAFIN.—On June 26th, at Liverpool-road, Chester, the wife of Lieut.-Colonel J. B. Hanafin, C.I.E., I.M.S., of a daughter

LEWERS.—On June 30th, at Castle Hill, Ilfracombe, the wife of Dr. H. B. Lewers, of a daughter.

LOWE.—On June 29th, at Rey Bridge, Lacock, Wilts., the wife of Dr. John Burman Lowe, of a daughter.

REID.—On July 4th, at Rodney-street, Liverpool, the wife of Andrew McKie Reid, M.C., F.R.C.S., of a son.

MARRIAGES.

CARR—BOXALL.—On July 4th, at St. James's Church, Abinger, Dr. Stephen Alan Carr to Irene, only daughter of Mrs. R. Boxall and the late Robert Boxall, M.D., of Ingleside, Abinger Common.

ROUSE—MURRAY.—On July 6th, at the Parish Church of St. James, Paddington, Dr. James Edward Colleton Rouse to Nancy Mary Louise, younger daughter of Dr. and Mrs. Richard Galway Murray, of Sussex-gardens, W.

DEATHS.

BRUCE.—On July 7th, at Harley-street, John Mitchell Bruce, in his 83rd year.

FENTON.—On July 4th, at Croft Lodge, Brackley, John Samuel Fenton, B.A., M.D. (T.C.D.), in his 68th year.

GALE.—On July 5th, Arthur Knight Gale, M.R.C.S., L.R.C.P., of South Mount-terrace, York, late of Woodseats, Sheffield, aged 70.

HARDENBERG.—On July 2nd, at Frederica-road, Chingford, Emile John Frank Hardenberg, M.R.C.S., L.R.C.P. Lond., aged 52.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Comments, and Abstracts.

THOUGHTS ON UNIVERSITY COLLEGE.

An Address delivered to the Assembly of Faculties of the College on July 4th,

BY SIR WALTER FLETCHER, K.B.E., M.D., F.R.S.,
SECRETARY OF THE MEDICAL RESEARCH COUNCIL.

[Sir Walter Fletcher began his address by regretting the impending resignation of the Provost, Sir Gregory Foster, and continued :—]

I think it a high and a quite unmerited honour that I should have been allowed, among so many distinguished guests to-day, to be your special visitor and to receive, as I have done on your behalf, the scholars, medallists, and prizemen of the year. They have well shown by their achievements how lively is the spirit of endeavour here, and how high the level of performance. We congratulate them heartily; and to them and to all the graduates of the year now passing on to the next stages of their chosen work we bring our warmest good wishes. To stand here as I do now, your visitor to-day, gives me emotion for private and personal reasons, of which I hope you will allow me to speak briefly. I cannot help reflecting that more than 80 years ago my own father came here as a student. He was born almost in the same week as that of the foundation of the College itself. Debarred from Cambridge by the test then imposed of signing the Thirty-nine Articles, he came to this place of free learning. Here he found great teachers like Arthur Clough in English literature, de Morgan in mathematics, Graham and Williamson in chemistry, and to those men and to others here he never failed to acknowledge a lifelong debt. He might have found mathematicians *technically more competent at Cambridge, though de Morgan* can have had no equals even there in the kind of inspiration he gave. As to chemistry, he could have found no practical instruction at all in either Oxford or Cambridge at that time. It was not till three years later that Prof. Liveing, at Cambridge, began his first practical class in a small cottage hired for that purpose.

Family and Personal Indebtedness.

Will you pardon me if I recall some of the memories on which my father was fond of dwelling? In his years here, just at the mid-century, University College was not far from the edge of the town, with many green fields between it and Hampstead. My father's home was then considered to be far in the country; it was among fields and gardens at the top of Denmark Hill. Transport from Denmark Hill was not then what it is now, though I may say that his elder brother, an engineer, had already made a steam road-car and had successfully driven it from Reading to Maidenhead in 1843. For my father the daily journey from Denmark Hill to College took too long. He hired rooms in Gower-street, and used to come in on Monday mornings by a horse omnibus from the bottom of Denmark Hill for the week at College. He did his light reading in the 'bus, and for that purpose he commonly used the monthly parts of "Dombey and Son" and then of "David Copperfield," in their green paper covers, as they were written by Charles Dickens in *his house at Doughty-street, half* a mile from here. One of my most prized possessions is the gold medal for chemistry my father gained here in 1851, receiving it, I suppose, at some such ceremony as this. My family piety impels me to boast that the runner-up for the medal on that occasion was Sir Henry Roscoe, whose friendship my father gained here and enjoyed for over sixty years. You will understand how keenly I feel the pleasure of being allowed to come to this assembly of the faculties, and of being able thus to acknowledge here my father's lifelong affection for this College, and his lasting gratitude for all he owed to it. I owe so much to him that his debt to you is mine. I can only attempt to repay it by the honour and respect I give to this home of young life and friendship, this great house of learning and research.

This family debt I owe to University College is by no means the end of my debtor's account. In my father's time, and for a quarter of a century longer, that inspiring teacher, William Sharpey, was Professor of Physiology and Anatomy here. Of his immediate pupils, Michael Foster passed from this College to found the school of physiology at Cambridge, and in large degree indeed to found the whole group of modern biological sciences there. While Burdon Sanderson carried fire from the same torch to Oxford, and Schafer, happily still with us, bore it to Edinburgh. From those missioners of Sharpey and of University College at those three centres have come living developments clearly traceable in their perennial fertility though quite incalculable in extent, and not only in Great Britain but throughout the world. But I dare not begin to say more of this now. Of Foster no Cambridge man can speak without gratitude, and no pupil of his without glowing affection. I have here again to confess for his sake an obligation to this College which I share with so many others.

The Greatness of Lord Haldane.

The Provost in giving his interesting record of the past academic year said rightly that this year has been momentous in the history of London University. The new constitution of which this year has *seen the birth, will bring fresh unity* and effectiveness to the University. In so far as it does that it cannot fail to enrich the opportunities of this College for adding fresh lustre to its long and unparalleled history of service—of service devoted from the first to all those ideals that rightly belong to university life and work in London. There must be many here to-day whose reflections have been deeply stirred not only by thoughts of this but by another event also within the past year, and just recalled to us by the Provost. I mean the death of Lord Haldane, who formerly gave devoted effort here as Vice-President of the College Council and whose desire, stronger perhaps than any other desire of his life, was to see and to aid the advancement of those great purposes for which this College stands. For much more than 30 years he had given time and work lavishly to the cause of university reform in London. The story of those long, intricate, and controversial labours lies on record. To-day we think of him as a past officer here whose life has ended just as the seal was being set upon what it had so long been his object to secure.

I am sure you will think it right that on this occasion, and in this assembly of university men, that we should hold Lord Haldane in special remembrance. It is surely true to say that no man of his own or any other generation has done more to promote the growth of university education in this country. He saw clearly that not only the soul but the material welfare and even the safety of Great Britain were being endangered by our national neglect of university education. Throughout his long life he saw clearly and taught strenuously the true ideals of university life. He toiled ceaselessly in hard labour by day and night through clouds of controversy, through banks of apathy, and among intricate mazes of political and financial difficulty until he had secured the foundation in enduring form of one part after another of our national university system. If we look back upon what he actually did, the tale is almost incredible. His work for London University for over 30 years makes a drama known to you all. The present university system in Ireland was due to his conception, hard work, and diplomacy, though he gave others the credit. The foundations of Liverpool University and of the other civic universities that followed it were due in large part to him. His was the chief hand in framing the university system for Wales. He was foremost among the founders of the Imperial College of Science, and his work and influence were vital for the beginnings of the University Grants Committee and the Scientific and Industrial Research Department. For most men, Lord Haldane's service to education would represent whole-time labour for a lifetime. Yet he did it as a labour of love, while he was engaged in a huge professional practice at the Bar, and later, while he was Secretary of State for War, the busiest and greatest we ever had, and while he was Lord Chancellor. Already, as each year passes, the truth about his work is becoming more clearly known. His multiple *achievements stand out in their mass as we recede* from them in time. Unlike so many of his colleagues in the public service, Lord Haldane had no arts of the demagogue, natural or acquired. He had no gift of voice, no picturesque appearance. Devoid of all art in self-advertisement, he offered to the public in his writings and speeches an aspect which to the half-educated had no practical message. Even in his professional work at the Bar his massive success was won not by words cleverly spun before juries, but by his intellectual advocacy before the trained minds of the highest courts. These deficiencies in personality, if they were deficiencies, account for the tragedies of his life which he faced with such dignity and unselfishness. In the words of Lord Haig, which only echo those of all professional soldiers, Lord Haldane was the greatest War Minister this country has ever had. In the face of entrenched conservatism and financial stringency, he created the Imperial General Staff, the Officers' Training Corps, the Territorial Army, and that Expeditionary Force which the German commanders admitted to be incomparably effective. Yet for want of a few bold words of truth, openly spoken by the political colleagues who best knew his work, the country lost his services at the very time when it was being saved by the fruits of his work and when our further need of him was so great. Even Haig, in the hour of his triumph, had not the bravery to pay openly to Haldane the written tribute I have just quoted. He permitted himself to be content at the time with paying him a secret evening call. But if the Cabinets Lord Haldane served and the Army he created have run the risk of losing the respect of posterity by their great sins of omission, we who belong to university life must not fail with them, and must openly declare our debt. Haldane's future fame is assured, for it stands on the rock of performance, and it will live when the lesser men who failed him will have been long forgotten.

University College and University Ideals.

Here at University College are surely both the conditions and the embodiment of the university ideals that Lord Haldane so strenuously upheld. Of those ideals, one of the chief is represented by the very fact that this red letter, or red gowned, occasion is called the Assembly of the Faculties. I take this as marking your attachment to the principle that all branches of knowledge should be brought in such close relation within a true university that there may be in each part a sympathetic understanding of the work of all other parts, of their mutual relations, their possibilities and limitations. This College has not grown as the modern universities of the country have in the main grown, by the successive grafting of new faculties on to schools of technical instruction. University College has been a complete University from the beginning, and was indeed for long the only complete University in the country, having a full Faculty of Arts, including Fine Arts and Architecture. From the beginning, too, your faculties have been in close association both in place and in spirit. Only so can the true function of a university be realised. Only by taking the whole realm of human thought and experience for its kingdom can it bring workers in all the divers fields into a full community, effectively impose its distinctive influence upon them, and imbue them with one spirit and one aim. That spirit of the university must be the sense of a fundamental unity of purpose residing in every kind of creative work, whether in art, in letters, or in science. That single aim must be the conscious direction of all the powers that spring from knowledge or skill towards the promotion of the highest ends. Here is the true religion, and this College has always been faithful to it. We can afford to smile at the old nickname of the "godless University," once given to it by a narrow and sectarian jealousy.

The intercourse of different faculties, so vital if the university spirit is to be maintained, is actually endangered by the multiplication of human knowledge. As the boundaries of the body of knowledge are extended by research, the individual workers at the points of growth find themselves more widely separated along the advancing periphery. Yet growth at any point may cease unless it receives fresh impetus from some cross-contact with other parts, perhaps apparently distant parts, of the field of knowledge. This gives a practical reason of daily importance for the close contact of faculties which only reinforces the spiritual reasons that come first. The distinguishing character of university work depends upon this university spirit; it does not depend at all upon the mere complexity of the instruction given. Yet the university fails unless the students within it learn not only the value of truth but the difficulty of gaining it. I have sometimes passed through your main entrance hall and seen the students hurrying about their business, and upon the walls the silent witness of those members of the College who gave their lives in the war. More than once, as I have seen this, I have thought of those words of Bishop Hall, of Norwich, in the seventeenth century, "God sells knowledge for sweat; as he doth honour for jeopardie." Knowledge indeed comes only by effort, and a true university will always inspire those possessing it to use it and spend themselves freely in the public service, not caring to count the risks.

University College and Its Neighbours.

If I may say one last word, it will be in reference to some benefactions within and near this place. Great new opportunities of applying in practical directions the knowledge gained here in the primary sciences have come in recent years to the College. Grouped near your [illegible] of primary
study are buildings for the appl[illegible] of engineering,
of technical chemistry, and to [illegible]
also upon the literary side. [illegible]
coöperation with the Med[illegible]
the road, while close at hand [illegible]
School of Hygiene and T[illegible]
already giving your ass[illegible]
taken, I think carelessly, [illegible]
kinds are not trul[illegible]
as such. I thin[illegible]
reason. We [illegible]
character to [illegible]
[illegible] the direct[illegible]
applied s[illegible]
for the [illegible]

it is continually suggesting new problems for research work of a fundamental kind.

As in private duty bound, I would here refer in particular to your new neighbour, the London School of Hygiene and Tropical Medicine, which is to be opened within a few days. From my own relations to the school I know how confidently it hopes for your continued coöperation, and how keenly it desires to join in service with you to its fullest power. It offers work to post-graduate students in all the wide and varied fields of knowledge that now serve preventive medicine. The School has been founded in order to bring all the resources of science to aid the protection, right use, and development of human life at home and throughout the Empire. These great utilitarian needs can be met rightly only in the light that scientific work begins. That work must have its roots in the disinterested pursuit of primary learning. Its close association with this place will bring to it, I hope, much more than an exchange of practical services. I pray that there may be realised within the new School, as within this College, the true and inner meaning of university work. The satisfaction of material needs is not to be our first consideration. Within a university it should become instinctive for us to see that the name of truth is hallowed before we seek our daily bread. I would that the School may learn that first lesson from your example and from your long tradition.

CLEAN MILK.

On July 9th at the Express Dairy Company's Farm at Finchley a demonstration was given of the making and filling of a new milk container which has been named the "Sealcone." This container is made of thick soft paper which is sterilised and made impervious to fluid by hot wax. The paper is passed through a forming machine, which makes the cone; the cone is then passed through a tank of hot wax, before being carried by machinery to the filling and sealing stations. Here an operator works a tap in connexion with the milk supply, so that the cone is filled with milk; it then is placed under a machine by which it is hermetically sealed. Thus every pint of milk can be delivered as between the dairy and the consumer without risk of contamination. The milk can be kept sweet in the containing cone for such a considerable period as a week, and the firm states that specially cooled milk shows no sign of deterioration in a month. The sealed cones can be sold to the public from the counter without a money deposit upon them, as there is no need to return them.

OVERHEARD AT THE SEASIDE.

To the Editor of THE LANCET.

SIR,—The following was overheard on the pier at the seaside:—

First female: "You should take *my* doctor's advice; he used to be just a doctor, an ordinary common doctor, you know; but now he's dropped all that; he's an *olive oil* specialist; he says it's the one thing; if you've a pain you *rub* it *on* outside, and you *drink* glasses of it."

Second female (much impressed): "There now! And it's in the Bible, too!"

I am, Sir, yours faithfully,
C. WILLETT CUNNINGTON.

Dollis-avenue, Church End, Finchley, July 4th, 1929.

SOUTH HANTS AND SOUTHAMPTON HOSPITAL.

On Friday in last week Prince George opened a new wing, named after Colonel Sir Edward King Perkins in acknowledgment of his services to the institution. The wing consists of two main wards named respectively after Dr. N. E. Aldridge, formerly senior physician of the hospital, and Mr. G. H. Cowen, senior surgeon, and six single bed wards named after benefactors. The extensions, which provide 84 additional beds, have cost £30,000. In declaring the new wing open Prince George spoke of the "Hospital House Ballot" which had produced £5000. The house was built by Southampton trade-unionists in their spare time, with materials supplied by the master builders, both labour and materials being given as contributions to the hospital.

Lectures

ON THE

PHYSIOLOGY OF GLYCOGEN

AND THE

RÔLE OF INSULIN AND EPINEPHRINE IN CARBOHYDRATE METABOLISM.

Delivered at the London Hospital

BY J. J. R. MACLEOD, M.B., LL.D. ABERD.,
D.SC. (HON.) TORONTO, F.R.S.,
REGIUS PROFESSOR OF PHYSIOLOGY IN THE UNIVERSITY OF ABERDEEN.

LECTURE II. (PART II).*

EFFECT OF INSULIN ON CARBOHYDRATE BALANCE IN THE RAT.

OTHER researches bearing on our present problem are those of C. F. and G. T. Cori, in which an attempt has been made to compare the fate of ingested glucose in white rats injected with insulin with that in uninjected rats, by determining the amount of sugar absorbed and that oxidised and stored as glycogen. When glucose was given, by stomach-tube, to rats previously starved for 48 hours, it was found that between 86 and 90 per cent. of the amount which disappeared from the gastro-intestinal tract in a period of four hours could be accounted for, a similar total balance being obtained when insulin was injected at the time of administering sugar.† There was a difference, however, in the manner of utilisation of the sugar, as was ascertained by comparing the relative amounts of glycogen formed and of glucose oxidised in the two cases. Relatively more carbohydrate was oxidised and less deposited as glycogen under the influence of insulin. The ratio, $\frac{\text{glycogen formed}}{\text{glucose oxidised}}$ changed from 1·38 in normal rats to 0·87 in those injected with insulin, and, since it was known that the liver glycogen becomes less under these conditions, it was concluded that the glycogen deposited elsewhere in the body either remains unchanged or increases somewhat.

According to the Cori's, therefore, excess of insulin leads to an increased sugar oxidation and they claim that the results are of such a quantitative character as to disprove the hypothesis that some unknown carbohydrate is formed. I am doubtful as to whether this claim to strict quantitative accuracy is justifiable. In the first place, the method used for determining the quantity of sugar absorbed from the intestine does not take into consideration any possible loss through bacterial decomposition, or a slowing in the rate of absorption, due to reduction in strength of the sugar solution as less and less remains in the intestine to be absorbed. The authors state, however, that they have shown that neither of these possible errors was involved. But even if the income side of the balance sheet could be vouched for, the dependability of the items on the expenditure side is questionable. For example, the calculation of the amount of carbohydrate oxidised is based solely on an average increase in R.Q. from 0·838 to 0·882, no change in oxygen consumption being observed. Consideration is not given to the possibility, that some change in the alkaline reserve of the blood and tissues, or a depression in the process of gluconeogenesis, may have been factors accounting for the altered R.Q. It is to be noted also that no allowance is made in the insulin-treated animals for reduction in the free sugar of the blood or of the liver, which these workers themselves have demonstrated, or of the muscles which Dale, Best, &c., say occurs. This would add something to the credit side of the balance sheet in the case of the insulin-treated animals.

Different Sugars not Affected Alike by Insulin.

I have referred to the first of the series of papers by the Cori's (1926),[10] and now let me say something about two more recent ones (1928). In the first of these,[11] comparison is made—in rats previously starved for 24 (instead of 48) hours—of the rates of absorption of glucose, fructose, and dihydroxyacetone, and of the balances between the amounts of each of these sugars actually absorbed and those accountable for by oxidation and glycogen formation.

It is stated that absorption is more rapid after 24 hours' starvation than after 48 hours, and that the manner of disposal of the absorbed glucose also differs. Both oxidation and glycogen formation were absolutely greater after the shorter period of starvation and relatively more glucose was oxidised, as evidenced by the quotient, $\frac{\text{glycogen formed}}{\text{glucose oxidised}}$ being 1, as compared with 1·38 for the rats starved 48 hours. The glycogen deposited in the liver, however, was the same for both, so that relatively more must have been formed in the muscles of the 48-hour rats. These results show a most remarkable change in the nature of the metabolic processes after different periods of starvation. But our chief interest at present is concerned with the effect of insulin, and in this connexion we must regard all three sugars. If the rate of absorption of glucose be taken as 100, that of fructose is 51 and dihydroxyacetone 65. Insulin was found to have no influence on these absorption ratios, and it produced little change on the percentage of the absorbed sugar which could be accounted for by increased carbohydrate combustion *plus* glycogen deposition. What insulin did do was to alter the proportion of the absorbed sugar disposed of by each of the processes. This is shown in Table IX. which has been compiled from the data in Cori's paper. In the case of all three sugars it is seen that insulin‡ caused less glycogen to be deposited in the liver and more in the muscles, the extent of the decrease in the former being about proportional to that of the increase in the latter in the cases of glucose and dihydroxyacetone, whereas in *that of fructose* the loss in the liver was proportionately greater than the gain in the muscles. Consequently increased combustion of carbohydrate was pronounced only with fructose. This means that excess of insulin in the body causes glucose and dihydroxyacetone to be locked up as glycogen in the muscles and fructose to be oxidised; leaving, in all three cases, practically no sugar available to be formed into glycogen in the liver. Utilisation of sugar in the muscles therefore runs ahead of glycogen formation in the liver. Cori puts it thus: "The processes of sugar disposal that are accelerated in the body by insulin are those mainly in the peri[illegible]ral tissues and involve both glycogen formation

TABLE IX.—*Disposal in the Body of Absorbed Sugars.*

* Part I. appeared last week.

† In later experiments the percentage recovered was higher in the insulin-treated animals.

‡ The dose of insulin was 15 units per 100 g. of rat.

and sugar oxidation." In so far as glucose is concerned, the conclusion drawn in the earlier papers, that insulin increases the amount oxidised, is therefore contradicted in this one.

In the light of these later results the fall in systemic blood-sugar following insulin injections is explained as due to increased utilisation in the muscles, by either glycogen formation or oxidation, running ahead of glycogen formation in the liver. But inasmuch as the gain in the one place practically balanced the loss in the other with glucose and dihydroxyacetone, it is difficult to see why any fall should occur in blood-sugar, unless we consider the lesser deposition of glycogen in the liver to be dependent upon inhibition of a process of gluconeogenesis. According to this view, the sugar which is certainly produced by gluconeogenesis in the liver during fasting will be suddenly cut off when insulin is injected, and the sugar absorbed from the intestine, which under normal conditions would be retained by the liver, is dealt with by the muscles, the blood-sugar falling because there is now no new sugar being produced by the liver. This view regarding the part played by changes in gluconeogenesis has been championed by Best, Dale, Hoet, and Marks, and was originally suggested in a general way by Laufberger.

In the last paper published by Cori and Cori [42] the effect of insulin was studied in the post-absorptive state, that is, after sugar absorption has been proceeding for four hours and the glycogen stores of the liver are being used up. The conclusion is drawn that insulin is a hormone that leads to a preferential utilisation of blood-sugar and, indirectly, of liver glycogen. The method used for calculating the amount of glycogen in liver and muscles at the beginning of the post-absorptive period is explained later on. The curious result is recorded in this paper that, whereas in uninjected rats 7·5 per cent. more carbohydrate disappeared than could be accounted for by oxidation, in animals injected with insulin 13·4 per cent. more was oxidised than could be accounted for. This result is given as final evidence that no unknown intermediary of carbohydrate metabolism can be formed in excess as a result of insulin, for, it is pointed out, if such were the case then the results should have gone in the opposite direction. But they prove too much. Indeed, so far as I can see, the results only show that comparisons between glycogen utilisation and carbohydrate combustion are not of sufficient accuracy to enable us to say whether or not some body, as yet unrecognised, is formed at some stage during the action of insulin.

Notwithstanding these criticisms, I should like to take this opportunity to express my admiration for the work of the Buffalo investigators. It may not have accomplished all that its authors had hoped for, but it has opened up new methods of approach and has demonstrated what many students of carbohydrate physiology have long suspected, that the rapid changes in glycogen content in the liver and the muscles are closely related.

Comparison of Different Views.

We may sum up the conclusions of these different groups of workers by saying that Lesser and the Cori's ascribe the entire effect of insulin to an increase in glycogen formation and carbohydrate combustion, whereas Best, Dale, &c., while considering that this explains the increased sugar loss in eviscerated animals, believe that in intact ones there comes into play another factor, which consists in an inhibition of gluconeogenesis in the liver. They point out that excessive gluconeogenesis and defective glycogen formation in the liver are the striking fundamental defects in diabetes and that insulin immediately rectifies these defects, its action on normal animals being merely an intensification of that on diabetic ones. This will therefore account for the raised R.Q., the subsequent depressed oxidation, the fall of temperature, and the depletion of glycogen, which are known to occur after very large doses of insulin, especially in small animals.

It is not easy, however, to harmonise all of the results of these researches, and this is particularly the case when we compare those of Best, Dale, &c., and the Cori's. When insulin was given, the former found that several grammes of glucose were utilised in the spinal preparation over and above the amount used without it, whereas the latter found in the white rat practically the same balances. Since some of the extra sugar which disappeared in the eviscerated spinal preparation was accounted for as coming from the liver, and since a shift of glycogen from liver to muscles occurred in the rats, this difference in results is partly accounted for, but by no means completely so.

Production of Unknown Sugar Derivative Increased by Insulin?

Although the suggestion which I offered in 1923 to account for the immediate disappearance of glucose from the blood which follows the injection of insulin—namely, that some unknown carbohydrate derivative is formed in considerable amount—has not therefore been sustained, either by experiments in which there is a much closer approach to quantitative accuracy than in those upon which I based the suggestion, or by direct chemical examination of the tissues, I am nevertheless disinclined to dismiss altogether the possibility that such a substance exists. It may not accumulate in sufficient amount to figure appreciably in the final balance between glucose disappearance and glucose utilisation, but it may be produced at an early stage of insulin action and then rapidly be transformed partly into glycogen and partly into some substance which is oxidised. That an unknown body related to carbohydrate must exist in mammalian muscle is suggested by the experiments of Fraser and myself, referred to in the first lecture, and it is possible that the substance which appears between glycogen and lactic acid when frozen muscle is pulverised and allowed to thaw is related to it. This intermediary substance may be of the nature of a trisaccharide having a lower reducing power than glucose and destructible by 30 per cent. potash. It is conceivable that such a substance may be responsible for the sugar which is excreted by depancreatised animals over and above that which can be accounted for as coming from the known carbohydrate reserves and from protein, and if such should prove to be the case, then it would be unnecessary to suppose that fatty acid is a source of sugar in diabetes. It is significant in this connexion that the unaccountable extra sugar excretion in diabetes occurs at early stages after the removal of insulin.

Respiratory Experiments on Rabbits.

As my reasons for still clinging to what may be called a remnant of my original hypothesis I have, so far, only shown why I do not consider it disproved by the results of others, and now I would like to dwell for a few moments on those of two researches done in my own laboratory which offer further reasons for my position. I will refer first of all to observations by Chaikoff and myself [43] concerning the effect of insulin on the respiratory exchange of rabbits, either while the animals were metabolising practically nothing but carbohydrate, or were deprived of this foodstuff. The former condition was provided for by feeding during several days with abundance of carrots and oats. The animal was then placed in a respiratory cabinet of the Benedict type, along with food, and the oxygen consumption and R.Q. measured from hour to hour during a period of six hours. Next day these observations were repeated with the difference that prior to placing the animal in the cabinet, it was injected with a sufficient dose of insulin to cause the blood-sugar to become decidedly decreased without, however, reaching the level at which hypoglycæmic symptoms supervene. Under these feeding conditions the R.Q. was found to stand practically at unity, indicating according to accepted doctrines that carbohydrate was alone being oxidised. Evidently the protein metabolism that must have been going on at the time was insufficient to affect the quotient measurably. Considering that the animals moved about to a varying extent while in the cabinet, the oxygen consumption was very steady from hour to hour, especially if we discount the first hour when a small error in measurement may have been involved.

It can be seen from the table of results that insulin had practically no effect either on the R.Q. or on the average oxygen consumption during the six hours. In some of the experiments (Table X.) it would appear that more carbohydrate was used on the insulin day, but the reverse is the case in others. These results were interpreted as showing that neither an increase in the combustion of carbohydrate nor an inhibition in gluconeogenesis could have occurred as a result of injecting insulin, leaving therefore increased glycogen deposition in the muscles as the only known process by which the sugar which disappeared could be accounted for. But this did not seem likely considering that the muscles were presumably already fully charged with glycogen. I have to confess, however, that these results are not so convincing as Chaikoff and I thought them to be at the time they were obtained. As Cori and Cori have pointed out, we did not know how much sugar actually disappeared and it may be that all which has to be accounted for is that represented by the fall in the blood and tissue-sugar percentages. During the first hour the blood-sugar percentage was reduced by about 0·070, and if we take the volume of the blood as 70 c.cm. per kg. and that of the tissue fluids as the same, then about 0·100 less sugar was present, an amount which would have caused an increase of 75 c.cm. in oxygen consumption if all of it had been burned. Now, if instead of taking the averages of the O_2 consumption over the whole period of observation, we compare the consumption hour by hour for each animal (*vide* original paper), then, with the exception of one out of five experiments, the increase during the first two hours in the insulin-injected rabbits is almost adequate to account for *the disappearing sugar*.

TABLE X.—*Comparison of O_2 Consumption and R.Q. in Rabbits With and Without Insulin.*

—	c.cm. O_2 per hr.	R.Q.	Total calories.	Total carbohydrate.	Difference.

3. Normal ..	720	0·72	16·00	0·22 g.	
Insulin ..	657	0·78	15·77	1·06 g.	+0·84 g.

In rabbits which were observed in the fasting condition, the results for O_2 consumption as well as R.Q., both when regarded as averages for the entire period of observation and when compared from hour to hour, show an undoubted increased carbohydrate combustion after insulin, and it is possible that the less evident effects observed in carbohydrate-fed animals is dependent on the principle that the glucose equivalent of insulin becomes very low in the presence of excess of carbohydrate.

Insulin and Glycogen Formation in Rats.

The other research has to do with the influence of insulin on glycogen formation. We have seen that it has definitely been shown by Best, Hoet, and Marks that glycogen is deposited in the muscles of eviscerated preparations when excess of insulin and of glucose is present in the blood, and the question arises, whether any of the sugar which disappears when smaller doses of insulin are given is to be accounted for in this way. To test this possibility, Barbour, Chaikoff, Macleod, and Orr [10] used the standard white rat in which, as Karczag, Macleod, and Orr had previously shown, the percentages of glycogen in liver and muscles are predictable within narrow limits. The results for previously fasted rats show *definitely that insulin does* not at first cause glycogen to be deposited; indeed, on the contrary, it causes the glycogen to become less both in the liver and the muscles. Since this result, in exaggerated form, is that which is obtained when sufficient insulin is injected to bring on severe symptoms of hypoglycæmia, it may be supposed that it was owing to the onset of these that the glycogen disappeared. All I can say is that no evidence of these symptoms could be obtained by the closest scrutiny of the animals, nor did the blood-sugar fall to the level at which they are observed to occur. The results of these experiments were shown in the chart of Fig. 2 and from them another interesting fact comes to light—namely, that the glycogen percentage rises in the liver at a later stage of insulin action, before there is any return of blood-sugar and while the percentage in the muscles is still falling. This is particularly marked when the dose of insulin is relatively small and is in confirmation of work by Frank, Hartmann, and Nothmann on fasted rabbits.[44] It indicates that although excess of insulin in the normal organism always causes already existing glycogen to disappear from the liver and, as we shall see immediately, always retards its deposition while carbohydrate is being absorbed from the alimentary canal, doses which are insufficient to lower seriously the blood-sugar have the ultimate effect of encouraging the deposition of glycogen formed by gluconeogenesis in the liver. This effect is a pronounced one in diabetes in which gluconeogenesis is very active.

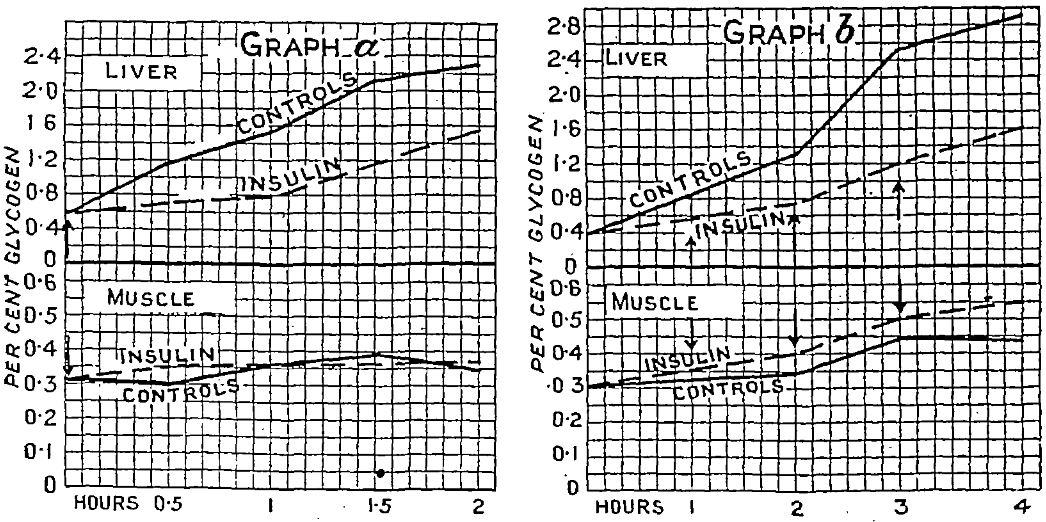
It is certainly safe to conclude that excess of insulin in the blood of fasting animals does not cause any of the sugar which immediately disappears from it to be deposited as glycogen, either in the muscles or in the liver.

Turning now to rats given insulin while maximal absorption of carbohydrate was proceeding (as the result of feeding previously fasted animals with all the starchy food they would take), we found that deposition of glycogen in the liver was invariably retarded and that extra glycogen was deposited in the muscles only when the dose of insulin was a very large one, or when the injection of smaller doses was repeated (Fig. 5). But even when this extra glycogen formation occurs in the muscle, it cannot probably be held responsible for any large part of the sugar which disappears, since the amount which fails to be deposited in the liver corresponds closely to the excess formed in the muscles. No evidence can be found in these results, which are sufficiently numerous to rule out errors of observation, to show that increased formation of glycogen in the muscles comes into play as a factor causing reduction of the blood-sugar when insulin is injected in moderate amounts. When the dose of insulin was very excessive during absorption of food more glycogen was deposited in the muscles, but, since there was a corresponding deficit deposited in the liver, all that this indicates is that insulin in large excess may cause a shift in the distribution of glycogen in the body. It is interesting, as Cori has proved, that excess of epinephrine causes a shift in glycogen distribution in the opposite direction—namely, from the muscles to the liver.

Present Status of Problem of Insulin Action.

We shall return to these experiments on epinephrine shortly, but meanwhile let me sum up the foregoing evidence with regard to the action of insulin. Taking all the effects which it produces, in diabetic as well as normal animals, we find that there is no known stage in carbohydrate metabolism, up to that in which lactic acid is formed out of muscle glycogen, that this hormone does not affect. It inhibits gluconeogenesis and stimulates glycogen formation in the liver of diabetic animals, whereas it retards glycogen formation in this organ in normal ones, except as a late effect when the animal is fasting. It reduces muscle glycogen when given in any dosage to fasting animals—and there is no basis for saying that this is because of the onset of hypoglycæmic symptoms—and has no effect on it when carbohydrate is being absorbed unless when an excessive dose is given. Under all conditions, both in normal and diabetic animals, it causes more carbohydrate to be oxidised, this being most marked in diabetic animals but so slight as to be almost imperceptible in normal ones in which absorption of carbohydrate from the alimentary canal is proceeding. The net effect of all these changes is to lower the percentage of sugar in the blood, notwithstanding that some of them, such as retarded glycogen formation in the liver, would rather tend to raise it.

FIG. 5.



Comparison of glycogen deposition in liver and muscles of rats injected with insulin with that of similarly fed control rats. One subconvulsive dose was injected at the beginning of Graph *a*, and several doses were injected in Graph *b*, as indicated by arrows. (Modified from Amer. Jour. Physiol.)

It seems to me, therefore, that these changes, which may or may not follow the administration of insulin, are secondary to some other fundamental change, and since it is impossible to demonstrate any influence of insulin on the sugar of the blood in vitro, either in the presence or absence of tissue extracts, we must assume that this hormone acts on some process that is dependent upon the structural integrity of the cells. Insulin must stimulate this process and lead, on the one hand, to a lowering of the tension of glucose in the cell—a glucatonia—so that sugar is removed from the blood, and on the other hand, to accumulation of some intermediary substance which, perhaps in association with phosphate—since this decreases in the blood as markedly as sugar after insulin—is then either oxidised or polymerised to glycogen.

I need not here refer to the several attempts which have been made to show that the fundamental change which insulin causes is a sensitisation of glucose, dependent on some rearrangement in the internal structure of the molecule. This may be so, but it has not been demonstrated, and so stands in much the same position as the hypothesis that some intermediary substance is formed. The possibility exists that one, or other or both of these hypotheses will be sustained by further researches, but at present all we know are the end-results of insulin, which consist in more rapid oxidation and lessened gluconeogenesis when no excess of absorbed glucose is present and in increased glycogen formation in the muscles when this is the case.

EPINEPHRINE.

It has in general been assumed that the hyperglycæmia which quickly supervenes upon the subcutaneous injection of epinephrine depends on a rapid glycogenolysis in the liver. A close scrutiny of the experimental evidence offers only feeble support for this assumption. Indeed, the majority of the experiments upon which it is based have obviously been imperfect in essential details, either in the methods used for determination of the glycogen or in the provision of controls. Whereas it is the case that the hyperglycæmia is sometimes of slight degree when epinephrine is injected into rabbits from which the glycogen content of the liver has been reduced to the lowest possible level, by fasting and strychnine, yet it is also well established, as was first shown by Pollak, that glycogen reaccumulates in the liver when the injections are repeated under these conditions. Pollak's results[12] were confirmed by Kuriyama[13] and, more recently, by Markowitz,[14] who used most drastic methods to rid the liver of glycogen before injecting the epinephrine. The injections were then repeated several times a day for periods varying from five to nine days and it was found that the blood-sugar was raised by the injection as greatly towards the end of the period as at the beginning, and that the liver, the muscles, and the heart still contained fairly large amounts of glycogen when the animals were finally killed. Thus, in a typical experiment in which the injections had been kept up for nine days following upon four days of fasting, a total of about 1 g. (1·05 per cent.) of glycogen was found in the liver and, taking the muscles as 40 per cent. of the body-weight (approximately 2 kg.), over 2 g. (0·265 per cent.) in the muscles, giving a total of between 3 and 4 g. of carbohydrate in the entire animal. Assuming that these amounts of glycogen were present throughout the experiment and that the immediate fuel for muscle is its glycogen, then it is obvious that gluconeogenesis must have been going on on a scale which was so large as to make it certain that fat as well as protein was being used for it. But the problem of the materials used in gluconeogenesis is not under discussion in these lectures.

The Cause of the Hyperglycæmia.

There are two possible causes for the increase in blood-sugar: a more rapid breakdown of the performed glycogen in the liver, or a decrease in the rate at which sugar is leaving the blood for the tissues. A third alternative—namely, that some of the increase depends on conversion of the glycogen of the muscles into sugar—is definitely ruled out. Thus Mann and Magath[44] and, more recently, Soskin,[45] have shown that no effect is produced on the blood-sugar level by injecting epinephrine into animals deprived of the liver. In this latter condition alone, the blood-sugar steadily falls and it continues to do so without any temporary delay following the injection of epinephrine. This, and other evidence, which I have referred to in another place, shows clearly that once sugar has passed from the blood into the muscles to form glycogen, it cannot be directly returned to the blood as sugar, by a reversal of the process. But this irreversibility does not necessarily mean that epinephrine is without influence on the glycogen present in the muscles. It might stimulate its natural breakdown into lactic acid which could then be transported by the blood to the liver to be reformed into glycogen there. As a matter of fact, Choi[31] found, by comparison of corresponding muscles of the two legs of the spinal cat, that continuous injection of epinephrine (intravenously) often caused the glycogen to be diminished, but he also noted that this only occurred when the preparation became hypersensitive, and fibrillary twitching was evident in the muscles. Some of the preparations were eviscerated and in these the blood-sugar was not affected by the injections, but it rose in those in which there was no evisceration. The general conclusion was drawn that injections of epinephrine do not deplete the muscles of glycogen unless fibrillation occurs, but it has not been sustained by the results of more recent experiments performed by Cori and Cori on white rats.

Experiments on Fasting Rats.

According to Cori and Cori[46] decreased utilisation of sugar by the muscles, and not increased hepatic glycogenolysis is responsible for the hyperglycæmia caused by epinephrine. On account of the originality and ingenuity of these experiments, we will consider them in some detail. The procedure was along the same lines as in the experiments on insulin, and the first series was on rats which had been deprived of food for 21 hours. The respiratory metabolism was then measured for three hours, when epinephrine (0·02 mg. per 100 g. body-weight) was injected subcutaneously and the respiratory measurements continued for a further period of three hours, after which the animals were killed and the glycogen determined separately in the liver and the remainder of the body. The R.Q. was the same following epinephrine as during the fore-period, but the consumption of O_2 rose by 17·8 per cent., indicating that the so-called calorigenic action of epinephrine does not necessarily involve carbohydrate combustion. This confirms previous work in my laboratory by Soskin.[47] The glycogen of the liver rose from an average of 6 mg. per 100 g. of rat to 42 mg., whereas that of the remainder of the body fell from 128 mg. to 71 mg. In other words, the glycogen of the liver increased by 36 mg. and that of the rest of the body decreased by 57 mg. The authors conclude that epinephrine causes a shift of glycogen from the muscles to the liver, and, since it is now an established fact that the latter cannot be directly returned to the blood as sugar, they have advanced the hypothesis that the glycogen must leave the muscles as lactic acid which is then re-converted into glycogen in the liver. To justify this hypothesis, it was necessary to show, first, that lactate is converted into glycogen in the liver and, secondly, that excess of lactic acid appears in the blood following the injection of epinephrine. The authors state that they have been able to fulfil both of these requirements. With regard to the former, it is true that Abramson, Eggleton, and Eggleton,[48] had failed to detect any increase in liver glycogen when *r*-sodium lactate, in quantities similar to those which would be produced by severe muscular exercise, was injected intravenously into dogs under amytal anæsthesia, but Cori and Cori state that this occurs when either the racemic or the dextrorotatory acid, or their salts, is fed to 24-hour starving rats. With regard to the second requirement, they had previously demonstrated a marked increase in the lactic acid of the blood in rabbits and cats following epinephrine,[49] but it may be remarked that no evidence is given that this may not have been due to anoxæmia or to shock.

Experiments on Rats in the Post-absorptive State.

Cori and Cori are careful to point out that although the circumstantial evidence strongly favours the view that the extra glycogen which appears in the liver in these experiments on fasting rats comes from that meanwhile disappearing from the muscles, it is also possible that a more active process of gluconeogenesis occurring in the liver might be the cause. They consider that this possibility is ruled out by the results of a second series of observations,[43] in which they injected epinephrine into rats in the post-absorptive state—that is, during the period following upon absorption of carbohydrate from the alimentary canal. The glycogen disappearance from the liver which would be occurring under these conditions was found to be changed by epinephrine injections into glycogen accumulation, accompanied by loss of glycogen from the muscles. On the assumption, which is probably justified, that gluconeogenesis will be latent when glycogenolysis is active, they conclude that alteration in the speed of the former process can play no rôle in accounting for the increased deposition of glycogen.

The procedure followed in these experiments is ingenious.

> Rats previously starved for 24 hours were fed by stomach-tube with 1·005 g. glucose per 100 g. of rat, which is the amount which would be absorbed in four hours.[41] During this period, measurement of the respiratory exchange showed how much carbohydrate was being oxidised and knowing, from previous experiments (1) that 80·6 per cent. of the absorbed glucose could be accounted for; (2) the proportion between the glycogen of the liver and muscles; and (3) how much glycogen is present both in the liver and in the muscles of 24-hour starved rats, it was possible, after making allowance for protein metabolism, to compute the amounts which must have been present in these places after absorption was complete. The injections were then made and the respiratory measurements continued for three hours when the animals were killed and the glycogen determined.

In four rats, in which saline was injected instead of epinephrine, an average of 220 mg. glycogen per 100 g. of rat was calculated to be present in the liver and 482 mg. in the rest of the body at the time of injection and these values were found (by analysis) to be 0·171 and 0·264 mg. three hours after it showing, therefore, decreases of 49 mg. and 168 mg. respectively. When epinephrine was injected in four other rats, glycogen increased in the liver to the extent of 26 mg. but decreased in the muscles to the extent of 208 mg. It may here be noted, however, that the values recorded for individual rats are very divergent; for example, in the control group the calculated values for the liver glycogen per 100 g. of rat, prior to injection, varied between 100 and 254 mg. and in the epinephrine group, between 178 and 257 mg., and at the end of the post-absorptive period in the controls the extrahepatic glycogen ranged from 315 mg. to 346 mg. and in the epinephrine group from 113 mg. to 130 mg. Surely it is somewhat risky to average figures that are so divergent when there are only four or five individual observations in each group. And when these loose averages are used, as the authors have used them, for balancing the carbohydrate which disappeared from the body (changes in glycogen and blood-sugar) with the carbohydrate which was oxidised (determined from the respiratory exchange), too much weight cannot be given to all the conclusions drawn from them. But, inasmuch as comparisons of individual observations in the different groups always show more glycogen in the liver and less glycogen in the muscles after epinephrine, it is no doubt justifiable to draw the general conclusion, that epinephrine in the dosage given reduces glycogen in the muscles and increases it in the liver. One would like to know, however, in view of Choi's results on the spinal cat, whether the muscles were hyper-excitable or were fibrillating.

It is next shown that there is an increased expenditure of energy (from 0·76 to 0·86 calories per hour) in rats injected with epinephrine in the post-absorptive state, two-thirds of the extra calories being furnished by fat combustion, and a third by carbohydrate. In the starving rats of the previous research all of the extra energy set free by epinephrine was found to come from fat, and since there was no oxidation of carbohydrates there was no depletion of the glycogen stores. In the starving condition there is merely a shifting of glycogen from muscles to liver, and the authors account for the practical constancy in glycogen between the twenty-fourth and the forty-eighth hours of starvation alone as due to a similar carbohydrate cycle.

Does Epinephrine Stimulate Gluconeogenesis?

These facts appear to the authors to make unnecessary the assumption that gluconeogenesis occurs as a process to maintain the glycogen stores, either during fasting or after epinephrine injections. They would have us believe that glycogen is a substance of no metabolic importance but which can be shifted about from muscles to liver according to the amount of epinephrine present in the blood. But it is difficult to harmonise such a revolutionary view with the known facts. Thus, it would mean that the 3 or 4 g. of carbohydrate (glycogen) which we have seen to be present in the body of a fasting rabbit which has been injected repeatedly with epinephrine for nearly two weeks is only some of that which was originally present, after having been shifted about between the muscles and the liver. The blood-sugar is merely the form as which the glycogen is shifted from liver to muscles and the blood lactic acid that as which it completes the cycle. No carbohydrate combustion therefore goes on under these conditions, so that no process of gluconeogenesis is necessary. The bearing of this conception on that of the chemistry of muscular contraction is not discussed, but it seems to me impossible to reconcile the two, unless we are to assume that all of the glycogen which is broken down during muscular contraction is carried as lactic acid to the liver and is there reconverted, through glycogen, into blood-sugar. In another paper the authors suggest the possibility, already made by me, that a process of conversion of fat and protein into carbohydrate may go on in the muscles, but in the present paper they point to the low R.Q. which is observed during fasting, as well as its failure to rise, in this condition, after epinephrine, as evidence that *no* carbohydrate is being oxidised.

It is very difficult to understand from the paper what the authors consider to be the physiological function of the shift of glycogen.

Another difficulty arises in explaining why it is that epinephrine always causes hyperglycæmia. One fact stands out prominently—namely, that increased glycogenolysis in the liver cannot account for it, even when there is a lot of glycogen in this organ. Thus, a hyperglycæmia amounting to 0·174 per cent. in three hours in rats following epinephrine injection would, as judged from sugar injection experiments, require the mobilisation of 750 mg. of liver glycogen (or an initial glycogen content of 20 per cent.), which is impossible. The authors think, however, that some mobilisation of liver glycogen may occur but is masked by the glycogenesis from the blood lactic acid, so that the glycogen percentage increases.

"Decreased utilisation of blood-sugar is one of the principal causes for epinephrine hyperglycæmia under post-absorptive conditions." Even although hepatic glycogenolysis is only proceeding at its normal rate, the blood-sugar will then rise. This decreased utilisation of blood-sugar does not mean decreased carbohydrate combustion, indeed, on the contrary, epinephrine increases oxidation of muscle glycogen and decreases blood-sugar utilisation.

Comparative Effects of Insulin and Epinephrine.

A very interesting comparison is made in this research of the effects of insulin and epinephrine on the behaviour of glycogen in the liver and muscles, and of the relative combustion of carbohydrate and fat, as calculated from the respiratory exchange. The following table gives a brief tabulation of the differences.

Glycogen Disappeared.

—	Total.	Per cent. derived from—		Calories and CHO oxidation compared with controls.	
		Liver.	Muscles.	Calories.	CHO.
	mg.				
Controls ..	216	23	77	—	—
Epinephrine	298	Increased	All	+24 %	+19·5 %
Insulin ..	329	43	57	Same	+97·3 %

Insulin therefore causes an equicaloric replacement of carbohydrate oxidation for fat oxidation. It "leads to a preferential utilisation of blood-sugar and indirectly of liver glycogen," whereas epinephrine increases the oxidation of both types of oxidation but diminishes the utilisation of blood-sugar and mobilises the muscle glycogen.

Experiments on Rats During Sugar Absorption.

The influence of epinephrine in the utilisation of blood-sugar was further studied in rats while absorbing glucose (third paper),[50] an advantage here, over observations made during the post-absorptive stage, being that carbohydrate metabolism is carried on mainly at the expense of the sugar that is circulating in the blood. The same dose of epinephrine, as used in the other experiments, now caused glycosuria which persisted throughout the observations, practically the same quantities of sugar being excreted during each of the four hours, although the blood-sugar steadily declined after the first hour, when it was at its highest. The rate of absorption of glucose was the same as that previously found in normal rats during the first hour following the injection, but it fell off later. Notwithstanding this slower absorption, more glycogen was deposited in the liver than in control observations, except during the first hour when the amounts were equal. This raises the question as to the cause of the glycosuria. Since it cannot depend on less sugar being retained by the liver, interference with the processes of sugar disposal in the tissues must be responsible. (The rapidity of these processes in a rat is called attention to; thus in a rat of 100 g. there are 7 mg. of glucose in the blood (blood-sugar 0·1 per cent.) and 1065 mg. are absorbed in four hours. If the blood-sugar rose to 0·158 per cent. only 28 mg. is accounted for in the blood.) By computation from the glycogen analyses and the respiratory metabolism, it was found that for every 100 parts of glucose absorbed, 10 parts less body glycogen were deposited and 5 parts less oxidised than in control rats. Of these 15 parts which failed to be utilised, 5 parts were stored in the liver as glycogen, 6 parts were excreted in the urine, and 3 parts retained in the body fluids.

It is stated that "after epinephrine injections, carbohydrate oxidation is carried on mainly at the expense of muscle glycogen" but, at the same time it is supposed that the utilisation of blood-sugar (and therefore of liver glycogen whence it comes) is diminished and so causes hyperglycæmia. It is very difficult to reconcile these facts, and the authors finally surmount the difficulty by concluding that "epinephrine has not a direct accelerating influence on carbohydrate oxidation. It merely mobilises muscle glycogen and it depends on the metabolic state of the animal (presumably on the insulin content of the tissues) to what extent the glycogen mobilised in the muscles is being oxidised."

GRAVES'S DISEASE AND THYROIDECTOMY.

BY W. H. C. ROMANIS, M.CHIR. CAMB., F.R.C.S. ENG.,

SENIOR SURGEON TO OUT-PATIENTS, ST. THOMAS'S HOSPITAL.

IN March, 1922, I published in THE LANCET the results of a consecutive series of 250 operations for exophthalmic goitre. At that time the surgical treatment of Graves's disease was not as firmly established as it is at present, or perhaps it would be more accurate to say that it was only just beginning to become firmly established. It had been practised to a certain extent before this period, but it is only really since about 1915 that its mortality has been so considerably reduced that it can be confidently recommended to severe sufferers from the disease. Since that date I have operated on another 500 cases of which a fairly complete record has been kept, and the present seems a not unsuitable occasion to inquire into the results.

Definition.

In all scientific or semi-scientific discussions it is as well at the commencement to endeavour to be quite sure what we are talking about, for it is obvious to all that between the fully developed case of Graves's disease, with all the symptoms well marked and extreme toxicity present, and the simple parenchymatous or adenomatous goitre, an infinity of different variations is seen, depending on which symptoms are or are not present, on whether the greatest effect of the disease falls upon the cardiac, nervous, or alimentary systems, and upon how marked the general toxicity is. We must therefore have a definition of Graves's disease upon which we can work and to which we can adhere; the simpler this definition is the better. I am, therefore, accustomed to apply this term only to those cases where in addition to the signs and symptoms so well known to represent thyroid toxæmia—i.e., palpitation, rapidity of pulse, nervousness, excitability, tremor, shortness of breath, sleeplessness, damp warm skin, &c.—there are also definite enlargement of the heart and definite changes in the eyes. This definition will be seen to rule out the simple forms of toxic adenomata, and adenomatous or parenchymatous goitre in nervous women. Naturally, the microscopic examination of a section of the thyroid gland is of the greatest use and importance. In the majority of cases where eye signs and cardiac enlargement are present the pathologist's report is that the thyroid gland shows the changes characteristic of Graves's disease. This is not, however, invariably the case, and even if the microscopic section resembles a simple parenchymatous or adenomatous goitre, if the above clinical changes are present, I think the case is deserving of the title of Graves's disease. One not infrequently sees patients in whom all the above clinical symptoms are well marked, the exophthalmos often being particularly noticeable, in whom little or no enlargement of the thyroid is present. Nevertheless, they should come within the scope of our definition, though as a matter of fact they are not necessarily cases which are particularly suitable for operation.

This definition does not, of course, rule out the so-called secondary Graves's disease, for the distinction between secondary and primary Graves's disease is one of considerable importance in use. Primary Graves's disease denotes those cases where the first appearance of the goitre and of the toxic syndrome roughly coincide, or at any rate where the goitre does not appear long before the symptoms. Secondary Graves's disease is the term applied to the quite common class of case where a parenchymatous goitre or more commonly an adenoma has been present and free from toxic symptoms for a long time, often many years, and it is not until after a long interval that the toxic symptoms appear. The former class of case, the primary ones, are usually the most severe and intractable, and it is in these that the tendency of the disease is specially to pick out the nervous system. In the secondary cases the disease is less severe and even more amenable to surgical treatment than in the former class. There is also a marked tendency in these latter cases for auricular fibrillation to set in sooner or later. Even when this occurs it is no bar to surgical treatment for, as will be seen later, such cases with fibrillating hearts are frequently amongst the most successful results obtained after thyroidectomy.

Operative Technique.

Of the last 500 consecutive operation cases ten have died as the result of the operation, giving a mortality of 2 per cent. One hundred and five of them were hospital cases, of which 95 were females, of whom four died, and ten were males, of whom none died. Three hundred and ninety-five were private cases, of whom 375 were females, five dying, and 20 were males, one dying. The hospital mortality thus is 3·8 per cent., the private mortality 1·5 per cent. The mortality among females also seems to be considerably higher than that among males. I do not think we need lay a stress on this differentiation in mortalities except to point out that the larger number of bad cases occur among women and that possibly the private patients in many cases have better and more prolonged treatment before operation.

I do not wish to dwell in detail on points in the operative technique, though there are certain general principles which cannot be too often or too strongly insisted upon. Of the many operations which have been devised and practised the removal of large portions of thyroid tissue seems to be the only one that is likely to survive permanently, ligature of thyroid vessels being of very little practical use. In the cases which are so bad that it is the only thing which can be attempted, ligature is not likely to do much good, whereas in the milder cases it is certainly not the best thing that can be done. The amount of thyroid tissue that should be removed is very important. It is practically never sufficient to remove one lobe and the isthmus; though this will create an improvement it is not the least likely to be curative. A portion—varying in amount—of the other lobe should always be removed as well. It should also be remembered that just as in such conditions as myxœdema it is not possible to specify straight away exactly what the proper dose of thyroid required will be, and different doses may have to be tried until the right one is found, so in removing thyroid tissue it may be very difficult to settle how much should be removed at the operation; the surgeon must therefore be prepared occasionally to find that he has not removed sufficient and that a further portion may have to be removed subsequently. This is naturally a thing to be avoided if possible. The danger of causing myxœdema is apparently very small, for estimations of the basal metabolic reactions in many of these cases before and after operation have shown that it is very uncommon to find it reduced below normal after thyroidectomy. It looks as though the smallest amount of toxic thyroid tissue is enough to keep the normal metabolism of the body going. One's aim, therefore, should really be to remove as much thyroid tissue as possible, stopping short, of course, of a complete thyroidectomy, but the limit is naturally set, and in the very bad cases very rigidly set, by how severe a procedure the patient's strength is equal to.

Another point in the operation to be avoided, if possible, is the leaving in the neck of small isolated portions of thyroid tissue, in such situations as upon the recurrent laryngeal nerve or around the superior thyroid artery. Though this procedure may make the operation a little easier these isolated portions left behind are very liable to undergo hypertrophy later on, and then they may give rise to a recrudescence of symptoms.

Anæsthesia and Pre-medication.

The choice of anæsthetic is undoubtedly of the greatest importance. In the first series of cases published we made use very largely of local anæsthesia. The late Sir Hector Mackenzie was very strongly of the opinion that this was of the greatest importance, and it certainly appeared as though this was largely responsible for the small mortality. Recently, however, we have been doing more and more of these operations under open ether anæsthesia with equal safety, though in the very bad cases—i.e., those with very grossly dilated hearts and very rapid pulses—local anæsthesia is still employed. By its means no one can certainly undertake cases to which one would not venture to give a general anæsthetic. Ether given by the open method, and as little as possible of it, is what we now employ in most of these cases. Patients are kept very light throughout so that a minimum quantity is required. A dose of morphia, or in many cases a large dose of paraldehyde in the rectum (a drachm for every stone of the patient's weight), can usefully be given an hour or two before the operation. Rectal ether we have used on occasions, though it does not appear to present any particular advantages over ether given by inhalation; I do not think intra-tracheal anæsthesia either necessary or advisable. It is not necessary, because it is very uncommon indeed to find any stridor or tracheal pressure or displacement in cases of Graves's disease, for the goitre is usually too uniform, while the disadvantages are due to the fact that it entails a very considerable depth of anæsthesia at the commencement for the passage of the catheter and also a considerable amount of manipulation of the neck.

It is only of recent years that it has been an almost invariable routine to give all patients before operation a preliminary treatment with Lugol's solution of iodine. Complete rest in bed on a full diet with Lugol's solution in doses of about 10 minims two or three times a day almost invariably results in considerable general improvement, especially of the pulse-rate and cardiac irritability. This improvement, however, is only of short duration, rarely lasting for more than two or three weeks, but it constitutes a very valuable form of preliminary preparation for operation. A few patients are encountered who are made worse by Lugol's solution and in whom therefore it cannot be used. Some surgeons make it a practice to select the cases suitable for operation and the best time at which the operation should be done by reference to how long the patient has had the condition altogether, feeling that certain periods in the duration of the disease are more suitable for operation than others. I have never been convinced that there is any really sure ground for this, and in most of these cases we have been guided far more by the clinical condition of the patient, the basal metabolic reaction, &c., than by the actual time that the disease has been in existence. It is a fact that such patients tolerate hot weather badly, and probably very hot weather is not the best time to select for operating on them. At the same time, in London at any rate, thick foggy weather is just as unsuitable for operations, and we have not therefore as a rule laid very great stress on these weather conditions.

Selection of Cases.

There are, of course, no fixed rules that can be laid down for the selection of cases suitable for operation, but it may be remembered that in quite a number of cases the condition is so slight or early that it may well be doubted if operation is really necessary, and that, on the other hand, there are a few cases (and only a few) which are so bad that an operation cannot be advised. In almost all cases it is wise to try the effects of medical treatment first, for though this may not necessarily be curative, it is an almost necessary preliminary to operation. The only features which can definitely be said absolutely to contra-indicate operation are marked failure of the heart and myocarditis, as shown by œdema of the feet, &c., and serious mental changes of the melancholic or maniacal type. Naturally, the usual nervous and emotional instability which is one of the features of the disease is no contra-indication, nor is auricular fibrillation. As I have already said, certain cases with marked auricular fibrillation (especially cases of secondary Graves's disease) do most remarkably well, the cardiac irregularity sometimes entirely disappearing within a few days of the operation, though one would prefer that they should be done, if possible, before bad fibrillation sets in.

There are certain cases which usually do not do very well after operation and in whom, therefore, operation is rather to be avoided if possible. The first group of these are children under 15. Fortunately, the disease is distinctly rare in children, though it is occasionally seen as young as 5 or 6 years old. Here the results of operation are usually disappointing. The second group of cases are those who, although they have marked signs and symptoms of Graves's disease, have no enlargement of the thyroid, not a very uncommon class. One may well wonder what the true pathology of these cases is. Remembering that the other ductless glands, such as the pituitary, are all involved to a certain extent in this disease, it is possible that in this type of case the influence of some other gland, again possibly the pituitary, is predominant, the thyroid only playing a very secondary part. However this may be, these particular cases do not appear in practice to get as much improvement after a thyroidectomy as do the more ordinary ones.

It must be remembered that Graves's disease is not necessarily a fatal disease. It is probable that quite half the cases, if untreated or only inefficiently treated, will survive and live for a long time, though the majority of these will certainly pass into chronic invalids unable in any way to lead an ordinary life and only hanging on to life precariously, while they are liable to be carried off by any intercurrent infection. Those that get well spontaneously will probably only do so after many years of ill-health. There is little doubt that operation, though not necessarily absolutely a life-saving measure, is the quickest and most certain way of getting these patients well enough to lead a normal life, and this question of saving time and ill-health is one of the most important influences which makes an operation desirable. The earlier the operation is performed and the fitter the patient is at the time, the quicker will this result be achieved.

Results of Operation.

Patients with Graves's disease as a class, both in hospital and in private practice, appear to be very easy to keep in touch with. They take a great interest in their own condition and are always pleased to report how they are and to submit to examination if necessary.

With regard to the results, one may say in general that it is the rarest thing in the world to see a patient who has had an *adequate amount* of thyroid tissue removed who is not very greatly improved. The worse the patients are before the operation the more marked the improvement is and the more pleased they are with the results as a rule, and it is a remarkable feature that the sense of well-being and the improvement in their subjective symptoms are generally even more marked than the amelioration in their physical signs. Thus most patients six months after the operation are able to lead a normal life, sleep and eat well, put on weight (in some instances too much), and express themselves as feeling perfectly well. Nevertheless, on examining them it is not uncommon to find that their pulse may still be a trifle quick—say, in the neighbourhood of 80 to 90—and they may still be somewhat jumpy and excitable. The exophthalmos disappears less than the other features, and if marked before the operation, though it will improve, it is not likely to disappear completely. These physical signs, however, tend gradually and slowly to vanish in the course of the first year after the operation. The dilatation of the heart which nearly all these cases have also disappears. Mentally and emotionally they become more stable. It must be remembered, however, that many of them are by nature and family history excitable, emotional, and unstable, and we can hardly hope by thyroidectomy to alter their constitutional tendencies, though we can well expect to return them to the condition they were in before the Graves's disease started.

The first few months after the operation is a very important period and the patients should be under careful observation for at least six months, while it is as well to warn them before the operation is performed that they must not expect to be well for quite this period. During this time they must *lead the quietest possible life*, avoiding all excitement, staying in bed late in the morning, and going to bed early at night; at the end of this period they may gradually begin to lead normal lives again. Once they have recovered sufficiently to lead a normal life there need be few restrictions on what they do, though long periods of strain and anxiety should be avoided if possible. The question of child-bearing is one which often arises, and once the pulse-rate has dropped persistently to below 90 and they feel and appear well there seems to be no objection to their going through pregnancies should they so desire. Many of these patients have had two or three children since operation. The risk of myxœdema following operation does not seem to be at all great, on the whole less than after treatment with X rays.

PSITTACOSIS,

WITH AN ACCOUNT OF CASES OF HUMAN INFECTION.

By A. P. THOMSON, *M.C.*, M.D. Birm.,
M.R.C.P. Lond.,
ASSISTANT PHYSICIAN TO THE GENERAL HOSPITAL BIRMINGHAM;
PHYSICIAN TO THE CHILDREN'S HOSPITAL, BIRMINGHAM.

Psittacosis is an epidemic disease of parrots, the chief symptoms of which are general debility, loss of appetite, and chronic enteritis. Its mortality among infected birds is very high and it is probably responsible for a large proportion of the deaths occurring among parrots soon after their arrival in Europe. This mortality forms a serious problem for bird-fanciers.

History of the Disease.

Boggs[1] states that the disease was first recognised in Germany by Ritter in 1879, but as I have been unable to consult the original paper I am not certain whether Ritter described the disease in man or only in parrots. However that may be, it was not until the years 1892–93 that psittacosis acquired serious clinical importance. At that time there occurred in Paris a large number of human cases of continued fever, one of the chief characteristics of which was pulmonary consolidation of unusual type. Accurate statistics cannot have been available but the epidemic was obviously a grave one, for contemporary physicians estimated the mortality at 45 per cent. of the patients attacked.

In view of the fact that Paris had but recently emerged from the great pandemic of 1889–90, it is not surprising to find that this new epidemic was at first regarded as an unusual manifestation of influenza, particularly as it was clear that in the great majority of cases abnormal physical signs were found in the lungs alone. According to Macaigne[2] it is to the French physician Dubief that credit is due for first directing attention to the fact that in the case of sufferers from this new and anomalous disease it was possible to trace close previous contact of the patients with sick parrots, which at that time were popular and fashionable pets in Paris. Shortly afterwards Nocard isolated a bacillus from the bone-marrow of affected parrots and established it as the cause of their disease; he also proved the toxicity of the organism for a large number of other birds and laboratory animals and showed that it could be recovered from feathers shed on to the floors of cages and that its virulence was retained for many months. An organism indistinguishable from Nocard's was first isolated from a human case by Gilbert and Fournier in 1896.

Since this Parisian epidemic of 1892 accounts have been published from time to time of similar outbreaks in different parts of Europe, particularly in Italy, Germany, and France, but I can find only one reference to the disease in the English journals and this is in the form of a short note written by Prof. Gulland[3] in 1924, which describes two typical cases of psittacosis in women, both of whom tended the same parrot. In Gulland's cases the diagnosis, though clinically certain, was not established bacteriologically and the first of the short series that follows appears to afford the only instance of the recovery of *Bacterium psittacosis* from a human case of infection in this country. In America, McClintock[4] has reported very fully a serious local epidemic beginning in a department store which undertook the sale of a consignment of parrots.

Case Records.

Case 1.—For information on several points in connexion with this case I am much indebted to Dr. J. A. Knott of Warwick, who had charge of her throughout.

The patient, a lady of middle age, first became ill early in July, 1928. For some days she suffered from indefinite malaise, complete loss of appetite, and frequent vomiting after meals. Despite these symptoms and the fact that she discovered that her temperature was raised, she did not go to bed. On July 9th she was very restless and an irritable cough developed; on the following day she became delirious and was unable to get up and her temperature in the evening reached 103° F. Three days later she seemed a little better and her temperature had fallen to 99°. During this period there was no vomiting or diarrhœa; the cough was more troublesome and almost incessant, but there was no expectoration. Physical examination was entirely negative.

On July 13th, when we saw her together in consultation, she was a little delirious but could be roused to answer questions sensibly. She complained of fairly severe headache and of a feeling of extreme illness. On examination some sharp crepitations were found at the apex of the left lung; in addition there was slight tenderness in the hypogastrium and the urine contained a little pus, but nothing else could be found to account for her condition. A Widal test gave a strongly positive reaction (1 in 1000 dilution paratyphoid B) and inasmuch as it was noticed that her pulse had remained slow (between 80 and 90) despite the fever, a diagnosis of typhoid infection was made.

On July 14th she was moved into a nursing home and her temperature persisted with slight fluctuations between 100° and 103° until the 23rd, when it fell by crisis to subnormal. During the whole of this period of ten days she was gravely ill with constant muttering delirium, incessant cough without expectoration, and sharp crepitant râles in the left upper lobe; she nevertheless took fluid nourishment extremely well.

At no time was the spleen palpable and never was there the slightest rash of any kind. Early on she was rather constipated and enemata were necessary, but towards the end of the febrile period there was slight diarrhœa. Pus was often present in the urine but it was known that she had had cystitis previously. On July 19th the right parotid gland became swollen and painful, and on the 23rd a small quantity of blood-stained fluid was aspirated from it and culture media were inoculated. After the critical fall in temperature convalescence was very rapid and eventually, after three months, complete; the swelling of the parotid gland disappeared in ten days.

We should probably have been content, in view of the positive Widal reaction, with the diagnosis of an unusual type of typhoid infection, had it not been for the fact that on discussing the matter with the family we were told that the patient's niece had made the remark that, "Auntie had what the parrot had had." On inquiry we found that a West African parrot which had been purchased some weeks previously had sickened subsequently and died shortly before our patient became ill. On further investigation it was found that the parrot was one of a number that had been imported together, a large proportion of which had already succumbed to the "parrot disease" and it seemed probable that our patient, who had cared for the bird while it was sick, had become infected by it. The cultures from the parotid gland confirmed this supposition for the bacteriological report that follows, although it does not conform in every detail with some of the published accounts of *B. psittacosis*, nevertheless shows that it belongs to the same group of organisms, individual strains of which are known to vary considerably in their behaviour in the laboratory.

There was slow growth on the usual solid media and on potato and slight hæmolysis on blood-agar; in nutrient broth a small petal-like growth developed upon the surface of the medium; no liquefaction of gelatin occurred and there was no anaerobic growth. The organism, which was in pure culture, was found to be a short bacillus with polar staining ends; in the early stages it was mainly Gram-positive, but after 48 hours' growth in vitro it became completely Gram-negative. The bacillus produced acid and a little gas with glucose and acid with mannite, but there was no reaction with lactose, saccharose, or dulcite. Litmus milk first became acid but in 24 hours rapidly became alkaline. There was very slight agglutination with paratyphoid B serum, but none with a serum of *Bacillus enteritidis* Gaertner. It was unfortunately impossible to obtain serum from the patient to test its agglutinating power against the organism isolated.

In March, 1929, while I was engaged in searching for further information in connexion with this curious disease I happened to describe this case to my surgical colleague Mr. H. H. Sampson, and he at once suggested that I should investigate the circumstances of several instances of mysterious illness that had occurred in a nursing home in Birmingham. My subsequent inquiries brought to light the following details:—

CASE 2.—Mrs. A., proprietress of a large nursing home, aged about 50 years, in November, 1928, purchased a parrot which shortly afterwards became ill with vomiting and diarrhœa. A veterinary surgeon was called in consultation and formed the opinion that the disease was not infectious to man and that no alarm need be felt on that account. Mrs. A. continued, therefore, to attend the parrot, frequently nursed it in her hands, and to keep it warm allowed it sometimes to sleep under a woollen jacket against her breast. The parrot eventually became so ill that it had to be destroyed. While attending the parrot Mrs. A. had an attack of what seemed to be simple bronchitis which kept her in bed for a few days. She appeared to be recovering, but a few days after getting up was seized with severe pain in her back and had to return to bed. During the last two weeks of her life she had a continuous temperature which varied between 100° and 105°F., with signs of diffuse bronchopneumonia in both lungs. It was noticed that the pulse-rate never exceeded 80 per minute to within about three days of her death in January, 1929, when it became very rapid. At the onset the bowels acted normally, but in a few days became very relaxed and finally she had incontinence of fæces. In the later stages of her illness there was retention of urine and she had to be catheterised; sweating was often profuse, abdominal distension was very marked throughout, and she vomited frequently after nourishment.

CASE 3.—A young woman of 27, by occupation personal maid to the proprietress of the nursing home (Case 2), assisted her mistress in the care of the sick parrot. On Jan. 17th, 1929, when her mistress was already gravely ill, she complained of severe headache and backache and her temperature was found to be 103°. At the onset of her illness she vomited frequently. Doubtful signs were found in the lungs and a tentative diagnosis of pneumonia was made, although there was no cough and respiration was not markedly increased. The pulse-rate varied between 100 and 110; sweating was profuse. During the next five days she had a high continuous temperature, between 103° and 104°; the pulse, however, remained relatively slow, at about 100 per minute. She was frequently delirious and had some diarrhœa. The diagnosis remained in doubt, but on the 22nd a rash was noticed and it was thought that she had scarlet fever, although she stated that she had had it twice previously. On that day she was sent to the City Hospital under the care of Dr. E. H. R. Harries, to whom I am much indebted for details of her subsequent progress.

On admission she was found to be of frail physique and in poor general condition. There was a good deal of nasal catarrh but the *fauces and tonsils were clean and showed* neither exudate nor injection. The tongue was clean, red, and dry, and there was no enlargement of the papillæ. There was a large patch of facial herpes. Across the abdomen and upon the back there was a punctate erythema, which Dr. Harries thought was probably a "flannel rash"; the *skin was generally moist*; *the urine was normal*. As there was no definite evidence of scarlet fever the patient was removed to an isolation ward and barrier-nursed throughout. A note made on her admission states that the first sound at the apex was soft and indistinct and the percussion note over the right lower lobe was impaired; in this area the breath sounds were harsh but there were no adventitious sounds.

On the following day she was very delirious and constantly attempted to get out of bed; she had an occasional cough. The abdomen was distended but no enlargement of the spleen could be made out; the rash had faded and tubular *breath sounds* with moist râles were now apparent at the right base. By Jan. 24th the rash had entirely disappeared, her respiration had become laboured, physical signs in the right lower lobe were more marked, and in the left lung expiration was noticed to be prolonged. Abdominal distension continued and she passed a good deal of flatus. *The tongue* was dry, brown, and cracked, and there was marked sordes. On Jan. 25th there was less distension but tubular breath sounds were present in both lungs with a large number of crepitations. She died on the following day; no autopsy was allowed.

During the whole of the four days that she was in the isolation hospital before her death the temperature was high and continuous and ranged between 105° and 102°. The pulse-rate reached 132 on the day before her death, but previously had averaged about 110 despite the high temperature.

In a personal letter to me about the patient, Dr. Harries says: "There was no évidence of scarlet fever; death was certified as due to pneumonia. In the light of what you say about the parrot and from a comparis[illegible] the [illegible] of S. R.'s case with Macaigne's [illegible] seems highly probable t[illegible] condition."

Case 4 [illegible] but it is worthy of [illegible] nursing home who [illegible] 2 and 3 and also with the parrot, suffered at the same time from an unusual and obstinate form of bronchitis from which she eventually recovered completely. The three cases from the nursing home were all under the care of one of my colleagues, with whom I have since discussed the matter. He has told me that their course was a very unusual one, and that at the time he was not at all satisfied with the tentative diagnosis of broncho-pneumonia. Although the responsibility of the parrot for their infection was not suspected during their illness or, indeed, until some months after the death of two of them, I think that the details that I have since been able to obtain leave practically no doubt of the true nature of their condition.

Clinical Manifestation of Psittacosis Infection in Man.

The first three cases described correspond very well with the text-book descriptions of psittacosis in man; the fourth may have been a mild infection. Clinically, the patients present evidence of septicæmia of the typhoid type complicated by unusual signs in the lungs suggestive of pneumonia. Vomiting at the onset is frequent and may persist; delirium is nearly always severe. The spleen is at times said to be enlarged, though apparently it was never so in any of my cases, and rose spots occasionally occur. Positive agglutination reactions with the typhoid group of organisms are sometimes met with but rarely to the marked degree found in my first case. An unusual symptom of diphtheroid stomatitis has been noticed in those who have practised what must be the difficult art of mouth-to-mouth feeding with parrots. The duration of the fever varies from 15 to 20 days and the total mortality is said to be extremely high, in the neighbourhood of 40 to 50 per cent., and even more than this in elderly people. It is a striking thing that while in parrots the lesions are limited to the alimentary tract, in human beings it is the pulmonary complications that are the most conspicuous features of the septicæmia.

The chief clinical point that emerges from this study is that anomalous cases of continued fever, in some ways suggestive of typhoid septicæmia with marked pulmonary involvement, should raise the question of the possibility of psittacosis infection.

Incidence of Psittacosis.

The paucity of references in English journals to psittacosis and its scanty treatment in the text-books show that in England it is a disease but rarely recognised; that its occurrence is as rare as its recognition is by no means certain. On the contrary, several considerations warrant the suspicion that this extremely serious condition may occur more frequently than is believed. Firstly, it is known that a number of imported parrots die of it; secondly, the infecting organism has been shown by many workers, particularly by Perry,[5] to belong to the salmonella group and to have close affinities with *B. paratyphosus*, *B. aertrycke*, and *B. enteritidis* Gaertner; there is no confirmation of McClintock's opinion that it is pleomorphic. It is further established that when removed from its host *B. psittacosis* can retain its virulence for a long period of time both in the dejecta and on feathers, and opportunities for infection must therefore be frequent, particularly among those who handle parrots. Thirdly, in human infection the symptoms are such that, unless they are fully aware of the existence of the disease, competent observers may be led to be content with an erroneous diagnosis of some form of pneumonia or of typhoid fever, as indeed would have been my own fate had it not been for the insistence of the niece of my patient (Case 1) on the correct diagnosis.

It is of practical importance to determine the manner in which parrots become infected. It has been suggested that the insanitary conditions which prevail in their journey from the tropics to Europe are responsible and, certainly, the fact that psittacosis is most common in newly imported birds supports this view. If this, indeed, be true it would be well for the responsible authority to insist on a period of quarantine for imported parrots before they are set free for sale. On the other hand, it may be that the sudden change of climatic conditions and from freedom to close confinement so reduces the general resistance of the birds that they fall a prey to invasion by an organism which they usually carry without ill-effect. If this view be correct any parrot in captivity may be a source of danger. To clear up this point I should be glad to receive swabs from dejecta of parrots for investigation. Lastly, I feel that the attention of veterinary surgeons should be directed to the extremely serious nature of psittacosis infection in man and to the established fact that it is generally acquired directly from sick birds (oddly enough, infection between individual patients seems to be rare though, of course, its *possibility cannot properly be denied*). The opinion expressed by the veterinary surgeon called into consultation on the nursing home parrot, the cause of infection of Cases 2, 3, and 4, was to me surprising, but I discovered that he may claim a certain amount of authority for it.

On turning to what appears to be a standard work[6] published so recently as 1920, I found that the authors do not regard it as proved that the disease of psittacosis can be transmitted to man and quote Leichtenstein, who says that "Epidemiological, clinical, and especially bacteriological evidence is not disclosed to prove that the infection of house epidemics of pneumonia, suspected of being psittacosis, did originate from sick parrots. The same house epidemics of pneumonia occurred not rarely without the intervention of parrots, and one may from this draw the conclusion that former psittacosis epidemics were nothing more than atypical pneumonia in which the sick parrot, accidentally present in the house, played no ætiological rôle."

The recovery of the organism in Case 1 of my series may, I hope, make a revision of this opinion possible.

THE INTRATHECAL TREATMENT OF PARASYPHILITIC AFFECTIONS OF THE NERVOUS SYSTEM.

By Dr. THEODORE BRUNNER,
PHYSICIAN IN CHARGE OF THE KUSNACHT SANATORIUM, ZURICH.

JUST as intravenous salvarsan treatment has taken a number of years to attain universal recognition, so a long period will be necessary before the indications and simple technique of the endolumbar treatment of meningeal syphilis will become generally appreciated. Up to the present, views upon its suitability are much divided. A constantly reiterated objection is that the same results can be obtained with intravenous salvarsan treatment, both clinically and in the effects upon the cerebro-spinal fluid. It is quite certain, however, that in 20 to 40 per cent. of cases a pathological fluid cannot be cleared up with intravenous salvarsan treatment, the figure varying with the quality of the general treatment and the age of the infection, and becoming more and more unfavourable with advance in the age. No fluid has ever been permanently restored to normal by intravenous salvarsan treatment after the fifteenth year of infection. According to Gennerich, these conditions have been completely changed by the endolumbar treatment.

The Technique and Its Purpose.

As early as 1912 Wechselmann and Marinescu made injections of salvarsan into the lumbar sac and noticed signs of irritation in the spinal cord, corresponding with the site of injection, as the drug remained in the same spot. Swift and Ellis reported in 1913 on their new method with salvarsanised serum, and Fordyce and Lafora obtained very good success in all stages of meningeal syphilis, especially in the optic atrophy of tabes. Fordyce also had many remissions in general paralysis, but the permanent success was less satisfactory. The Swift-Ellis method has proved inefficient for older and deeper-lying parenchymatous processes in general paralysis and its preliminary stages in cerebral syphilis and in latent processes. The superficiality of the effect is easily explained by the very small quantity of salvarsan used in the Swift-Ellis method: less than ⅓ mg. The small dose of salvarsan also explains the absence of excitatatory effects from this method, even in cases of severe spinal change.

In 1913 Gennerich began his treatment of syphilis of the central nervous system. He had ascertained, on the basis of many years' study, that, even in recent cases, neither clinical improvement nor benefit to the fluid could be obtained, in spite of energetic salvarsan treatment. Often, indeed, the condition became worse. He therefore decided to attack the syphilitic process not only through the blood but also through the fluid. He did not, however, use a serum for this purpose, but mixed the fluid which he took from the lumbar sac in quantities of 50–90 c.cm. with neosalvarsan and then let about two-thirds of this salvarsanised fluid run back again in the hope that, by this means, the salvarsan would reach the seat of the disease more effectively than if he left its distribution in the fluid to the existing limited circulation. The success of this treatment showed itself immediately. Whereas up to that time only 36 per cent. of cases of cerebro-spinal syphilis could be cured by intravenous treatment, Gennerich's figure rose to 76 per cent. Encouraged by this, he proceeded to treat the metaluetic process, with the same good results. With intravenous salvarsan treatment he was able to produce normal fluid and freedom from symptoms in three cases of early general paralysis; in six cases he got an improvement in health without cure of the fluid, while ten cases remained uninfluenced or grew worse. The endolumbar treatment, on the other hand, showed that out of 26 cases of tabo-paralysis remission was attained in 20 cases and that 5 cases were able to practise a profession.

Gennerich found that the success of the treatment depended upon the quantity of the dose. As it had been shown that the reliable maximum dose of salvarsan for a spinal cord suffering from pathological degeneration could only exercise an inadequate therapeutic influence on the brain, and that the brain could bear much higher doses without complications, the problem was to find out a means by which both processes could be treated simultaneously. This Gennerich attained through his double-puncture treatment. By this means it became possible to carry effective quantities of salvarsan into the cerebral fluid while the sensitive spinal cord did not come into contact with them for some time. For this purpose two punctures are made simultaneously, an upper one in the region of the lower dorsal cord and a lower one near the sacrum. From the upper five to six c.cm. are run out into a measuring-glass; from the lower 50 to 80 c.cm. or more, according to the body-weight of the patient. To the fluid obtained from the upper puncture is added a quantity of neosalvarsan varying from 1 to 3 mg., according to the disease process to be treated. If there is coincident tabes, ¼ to ¾ mg. of neosalvarsan are added to the fluid taken from below. After a thorough mixing of the fluids, first the upper and then the lower are run back. The head and upper part of the trunk must be kept low for 24 hours afterwards. Only about two-thirds of the lower fluid is reinjected, as there has been an excess of pressure, and withdrawal has a very favourable effect. The highly salvarsanised fluid has never been known to pass down into the caudal region of the lumbar sac and cause harm to the spinal cord. In the early stages of syphilis, in latent meningeal processes, in diffused syphilitic meningitis, and in the varied and more or less complicated symptoms such as attacks of cramp or disorder in the region of one or more cranial nerves, the cure of the fluid is very simple indeed. Since the introduction of double puncture it has been carried out in a far shorter time and usually with half the number of treatments required with simple puncture.

As soon as it is known what dose the degenerated spinal cord can bear (it varies between ¼ and ¾ mg.), the treatment can be carried out without any difficulty or complication. As the brain can bear more than five times as much as the dose mentioned for the spine, it is obvious that double puncture treatment should be used to the fullest extent if all cerebral disease processes are to be removed as rapidly as possible. That this treatment has led to a considerable advance in results may be seen from the following figures extracted from Gennerich: (1) cerebrospinal syphilis was cured with the simple endolumbar treatment in 76 per cent. of the cases; with the double puncture treatment in 100 per cent. (2) For prætabes and tabes the corresponding figures are 73 per cent. and 100 per cent. (3) For optic atrophy in tabes the double puncture treatment showed an improvement or cessation of active disease in two-thirds of the cases. (4) In 31 cases of general paralysis and tabo-paresis professional capacity was restored or far-reaching remission attained in 80 per cent. and the fluid was restored to normal in 55 per cent.

In our own series 50 per cent. of the cases of general paralysis and tabo-paresis were able to carry on their professions. Dementing cases of general paralysis are the most suitable for endolumbar treatment; the expansive cases offer greater difficulties for purely technical reasons, on account of the psycho-motor restlessness. The demented forms seem to involve more superficial meningitic processes; the expansive forms evidently go deeper into the parenchyma and for this reason do better under malarial therapy. If the symptoms of the illness have been manifest more than three to eight months before treatment is begun, there is little hope of success. As the case improves clinically so the fluid shows retrogression or disappearance of the positive Wassermann, albumin, and cells. If the treatment is broken off too early there is always a rapid deterioration.

Duration of the Improvement.

Gennerich reports cures lasting up to four years. We have a case of pronounced general paralysis that has been in complete remission for five years. Other patients can carry on their profession from six months to two years after treatment. Professional capacity could be attained in about half the cases and a far-reaching improvement in one-third of the remainder, so that no paralytic has been detained in my sanatorium since the introduction of endolumbar treatment. All patients treated by us live at home and come in at intervals of one to three months, or even longer, for two to four days' treatment.

Simultaneously with the endolumbar treatment, the patient undergoes an intravenous salvarsan treatment alternating with bismuth and iodine.

Whether or not a real cure of general paralysis can be attained with this treatment cannot be said with any certainty. Cure is anyhow only conceivable in quite recent cases, and, provided that the two methods, endolumbar and intravenous, cover the area of the disease.

Disease of the Spinal Cord.

The most difficult field of application for endolumbar treatment is, without doubt, spinal infection, where, owing to degenerative changes, the cord can only bear about a quarter of the endolumbar dose which has been proved safe for a healthy spinal cord. In the presence of all metaluetic processes, tabes as well as myelitis, the salvarsanised fluid penetrates much more easily into the nerves, and may therefore very easily injure them and thereby cause a cessation of function which can only be set right with difficulty if at all. The greater the inflammatory changes in the fluid—i.e., a high cell count—the higher can be the endolumbar dose, and the greater the diminution in the meningeal inflammation, the more urgent is the restriction of the endolumbar dose within those limits which experience has proved to be safe; that is to say, 0·5 mg. to 60 or 80 c.cm. of fluid, or still less if possible. Gennerich has succeeded in proving the permeability of the pia in general paralysis, tabes and optic atrophy, and shown the essential importance of diffusion of the fluid in setting up metaluetic processes. In treating all late stages in the central nervous system, it is essential to understand this diffusion, as it is otherwise impossible properly to estimate the dose for endolumbar treatment.

Indications for Endolumbar Salvarsan Treatment in Tabes.

For all cases of stationary tabes with normal fluid specific treatment and endolumbar treatment may be used. We treated a case experimentally with the endolumbar method and were able to convince ourselves that, when symptoms had existed for more than five years, neither an appreciable improvement in the ataxia nor any considerable diminution in the attacks of pain could be achieved. In all those cases, however, where there are slight changes in the fluid, the process is progressing slightly or severe attacks of pain occur, endolumbar treatment should be tried, as with careful administration it may lead to very far-reaching improvement.

In gastric tabes also early treatment may lead within a short time to a complete removal of the disorder and, finally, to a definite suspension. The effect of endolumbar treatment on older cases of gastric tabes is exceedingly varied. Isolated cases are freed from disorder after one or two treatments, but the great majority prove uncommonly stubborn. Many react with very severe crises, so that they are no longer fit for treatment without special preparation. Gennerich gives them a preliminary paravertebral injection of antipyrin (15 per cent. alcoholic solution with novocain), which facilitates the subsequent endolumbar treatment.

The treatment of degenerative optic atrophy is very gratifying and improvement may be expected in two-thirds of the cases. The dose must not exceed 1 mg., as the degenerated optic nerve shows the same irritability as the degenerated spinal cord.

If in the course of tabes severe changes take place in the fluid (strongly positive Wassermann, gold test, and mastisol curves, and large albumin values), pointing to cerebral involvement, double-puncture treatment is indicated. In simple cases of tabes the single puncture treatment suffices.

It has been contended in Germany that endolumbar treatment is dangerous, but this is not correct. According to Gennerich, the mortality-rate is 0·2 per cent. provided asepsis is complete; complications can be excluded with certainty if technical skill is attained. To secure this and to obtain the necessary knowledge of the most important question of dosage, any practitioner who wishes to use endolumbar treatment must undergo a thorough, practical introduction to the method. Temporary spinal irritation only occurs as a complication in about 3 to 5 per cent. and exercises no influence upon the final result of the treatment. Occasionally after the first treatment the Herxheimer reaction appears as attacks of cramp or acute relapse, but this is never more than temporary.

Still more important than treating the manifest metalues is preventing it. The premonitory symptoms of meningeal inflammation are known to occur in the earliest stages of syphilis and to carry on the disease process—according to the proportion between virulence and resistance—while the patient goes his way for many years, suffering no inconvenience, unwarned and free of misgivings, towards an unhappy fate and chronic illness. By investigating the fluid at the proper time the threat could be recognised, and treatment given which would guarantee certain cure of all latent meningeal processes.

SELF-RETAINING TUBES FOR THE OPERATIONS OF CÆCOSTOMY AND CYSTOSTOMY.

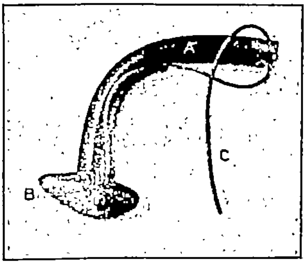
By F. WILSON HARLOW, M.B. Durh.,
F.R.C.S. Eng.,

SURGEON TO THE ANGLO-SWISS HOSPITAL, ALEXANDRIA, EGYPT;
LATE RESIDENT SURGICAL OFFICER TO THE ROYAL
NORTHERN HOSPITAL, LONDON.

THE operation of cæcostomy is undertaken, more often than not, under the most adverse surgical circumstances as regards the general condition of the patient; or else it is performed as an adjunct to a larger and often drastic abdominal operation. The time factor is therefore of peculiar importance. From my consideration of the results of others, and from my own experience, I observed that unless a fairly considerable time was taken for careful suturing of the cæcum around the tube the result was unsatisfactory; both in the deflation of the large gut and lower ileum in the early stages, and in the fistula produced after removal of the tube.

I therefore endeavoured to devise a more rapid technique for my own use, and as a result the cæcostomy tube illustrated was constructed. Briefly, it consists (Fig. 1) of a stout rubber tube A, 1 cm. in diameter, with a wall 0·8 cm. thick. Attached to one end is a bag B, of thinner rubber, like a miniature air ring in appearance and structure and 6 cm. in diameter. A supply tube C is connected to B, and runs alongside the main tube A; it is of a calibre equal to that of the nipple of a record syringe. The technique of the operation is as follows:

FIG. 1.



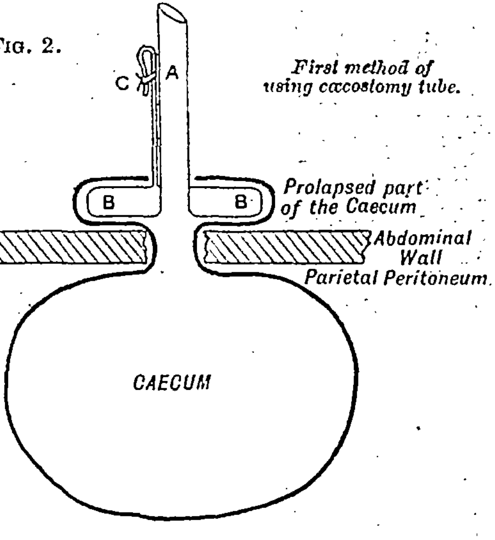
Cæcostomy tube.

A 5 or 10 c.cm. syringe is filled with sterile water and fitted by its nipple to the tube C. The bag or rubber flange B is now distended until quite hard and firm by driving home the piston in the syringe. The amount required to produce this distension is noted. The syringe is disconnected, after sucking back the fluid from the bag, and its contents are discharged. The syringe and rubber cushion flange are thus completely emptied.

Filled with the required amount of sterile water, the syringe is once again connected to the supply tube C, but the piston is not driven home. The collapsed cushion flange is folded on itself into four layers and held in this position by lightly-clamped sponge-holding forceps or large artery forceps. The actual operation is now commenced. The routine muscle-split incision is made not more than three inches long, and the peritoneum is picked up and divided in the usual way. The cæcum is sought and a portion of its anterior wall brought out of the wound by the fingers, aided by mouse-toothed Porier's forceps or Lane's forceps. These forceps are then attached to this protruded portion of the cæcum at either end of the wound so as to anchor it in position, and gauze is packed around to prevent soiling of the wound edges.

A purse-string suture is introduced into the cæcum enclosing an area 2 cm. in diameter, which is then incised longitudinally for almost its full extent. The collapsed cushion flange of the tube, held folded in the forceps, is immediately inserted into the cæcum. The forceps are then taken off and the purse-string suture rapidly tied. The piston of the record syringe is driven home, thus converting the collapsible rubber bag into a firm flange which effectually anchors the protruding portion of the cæcum in position. The syringe is disconnected and the supply tube doubled on itself and tied with any available ligature material. The protecting gauze is then removed and a silkworm gut suture introduced through all the layers of the abdominal wall at either end of the incision. When these are tied, the abdominal wall fits snugly round the prolapsed piece of the cæcum. Except for dressings and the attachment of a tube by means of a glass connexion to the distal end of the cæcostomy tube, the operation is now completed.

FIG. 2.



The main tube A is either made curved at right angles 3 to 4 inches from the cushion flange, as shown in the illustration, or else quite straight. In the latter case it can be divided at a convenient distance from the wound, and a rectangular glass connexion fitted; personally I find this the more satisfactory method.

The cæcostomy tube can be removed when required by aspirating the water from the cushion flange with a record syringe fixed to the supply tube. It will then be found to slip out quite readily. The larger size of the cushion flange when distended, in contrast to the glass flange of a Paul's tube similarly used, holds open and from the first prevents any possibility of occlusion of the fistula produced. Also it will be found that a larger permanent fistula (lined by mucous membrane) eventually results after removal of the cæcostomy tube.

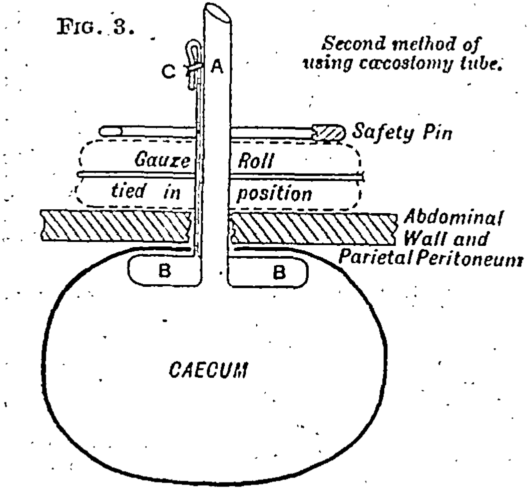
Fig. 2 shows a sectional view of the cæcostomy tube in position at the end of the operation.

This method of using the tube is only possible when the cæcum is sufficiently mobile to allow a pouch to be brought through the abdominal incision. For descriptive purposes it has been labelled the first method of using the cæcostomy tube.

When the cæcum is fixed and immobile, and a pouch of its anterior wall cannot be brc [illegible] the abdominal incision, an equally satisf[illegible] can be as rapidly produced by a slight variation of the technique. The modifications are as follows.

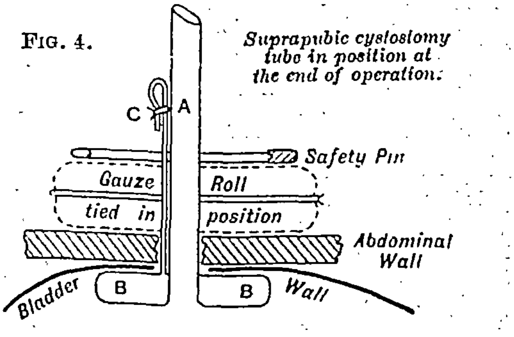
A somewhat larger incision will, as a rule, be necessary. A suitable portion of the anterior cæcal wall is then anchored at the bottom of the wound by grasping either end of the part exposed with Porier's forceps. These forceps are now held by an assistant, and the general peritoneal cavity is protected from soiling by gauze packing tucked under the wound edges. The insertion of purse-string suture and cæcostomy tube is carried out as before. The assistant now removes the Porier's forceps and packing, and applies traction to the cæcostomy tube. The anterior cæcal wall, which has been spread out over the upper surface of the distended cushion flange, is thus brought firmly against the parietal peritoneum. The two silk-worm gut sutures are now inserted and tied; and one or two large safety-pins are fastened into the main tube one inch from the wound, roughly one and a half inches distal to the cushion flange. If two safety-pins are used they are placed at right angles to each other. While the assistant still maintains traction on the cæcostomy tube, a roll of sterile or iodoform gauze is wound round the tube between the abdominal wall and the safety-pins and fixed firmly in position by tying some ligature material around the roll after encircling it several times. The safety-pin constitutes an external flange, and the roll of gauze and layers of the abdominal wall a washer between it and the internal cushion flange.

FIG. 3.



The anterior cæcal wall is thus maintained in contact with the parietal peritoneum, to which it forms adhesions around the opening for the tube. To ensure continuous close contact between these layers of visceral and parietal peritoneum, the gauze washer should be supplemented at each dressing, while traction is exerted on the cæcostomy tube by a nurse or assistant. The cæcostomy tube can be removed as readily as in the previous cases, after removing the water from the cushion flange, when the adhesions are firmly established. An equally satisfactory fistula will result. It was in experimenting on these cases in the cad [illegible] that the advantages of a known volume [illegible] an uncertain volume of air were dis-

FIG. 4.



covered, and water is therefore now used in all cases instead of air.

Fig. 3 illustrates a sectional view of this method, called for descriptive purposes the second method of using the cæcostomy tube. The tube, as illustrated and described, is the size found most suitable for well-developed adults. It is especially useful when employed according to method II. in the case of an obese patient with a thick abdominal wall. For emaciated and less well-developed patients it will be found too large and cumbersome, and for these cases a second size of tube has been constructed, smaller in all its proportions. The tube A is 0·75 cm. instead of 1·0 cm. in diameter, and 0·2 cm. instead of 0·3 cm. in the thickness of its wall. The diameter of the cushion flange is 4 cm. instead of 6 cm.

A New Pattern Cystostomy Tube.

A cystostomy tube has also been produced on exactly the same principles. The diameter of the cushion flange B is 4 cm., the main tube A has a wall 0·3 cm. thick and a bore of 0·5 cm. The supply tube C, which also runs alongside the main tube A is identical with that in the cæcostomy tube—namely, just large enough to fit the nipple of a record syringe accurately.

It is not necessary to describe in detail the operation of cystostomy and the insertion of the tube. Before beginning the operation the collapsed cushion flange is folded on itself in four layers, and held in this position by a lightly-clamped pair of artery forceps. A record syringe containing the known quantity of fluid required to distend completely the internal flange is attached to the supply tube. The bladder is reached and opened in the routine way, and the folded cystostomy tube thrust in. The artery forceps are removed and the flange distended by discharging the water from the syringe down the supply tube into it. The syringe is removed and the supply tube doubled on itself and tied off as in the operation of cæcostomy. The operation is now completed by suturing the recti abdominales and sheath, together with catgut above and below the tube, and similarly closing the skin incision with silk-worm gut or clips. It is probably safer to insert a small drain to the suprapubic space, though lately I have been omitting this without any harmful results. Finally, whilst an assistant applies gentle traction to the tube, a safety-pin and gauze roll are applied, exactly as described in the second method of performing cæcostomy (Fig. 4). The drainage of urine has been found to be more satisfactory than with the other types of cystostomy tubes even when no automatic aspirating apparatus was used.

The collapsed cushion flange, folded as described, can be inserted through an opening in the bladder of less than half its diameter in the distended condition. In consequence no sutures in the bladder wall are necessary to retain it firmly in position once it has been inserted, and urine does not leak around it if the pin and gauze flange are properly fixed. So far these cystostomy tubes have remained continuously in position and drained satisfactorily until it was decided to remove them. After aspirating the water from the cushion flange with a record syringe they come away easily and painlessly, only quite gentle steady traction being required to effect their removal.

The majority of surgeons will admit that all the usual types of cystostomy tubes can and do become displaced at times, however careful the nurses and patients may be. Cystostomy patients are very often mentally unable to assist at all in preventing this. Such minor catastrophes are not only alarming to the patients themselves but, as they often occur at the most inconvenient hours of the day or night, they are also productive of much annoyance to the busy surgeon. There are, however, already so many forms of cystostomy tubes designed for the operation of suprapubic cystostomy that it was, after considerable hesitation, that I had the temerity to suggest an addition to their number. It was only the fact that so far I have never had to replace one of this particular variety that finally led me to do so.

All forms of the tubes described are made for me by Charles F. Thackray, Surgical Instrument Maker, 110, High Holborn, W.C.1, to whom I am indebted for assistance in the experimental stages.

Clinical and Laboratory Notes.

CRUCHET'S "ENCÉPHALOMYÉLITE SUBAIGUË DIFFUSE"

AND EPIDEMIC ENCEPHALITIS LETHARGICA.

BY CONSTANTIN VON ECONOMO,
PROFESSOR OF PSYCHIATRY AND NEUROLOGY IN THE UNIVERSITY OF VIENNA.

IN the winter of 1916–17 I made observations on a small epidemic that occurred in Vienna. The infection was one which had not been known previously. It is a matter of common knowledge that on April 17th, 1917, I delivered a public lecture and showed patients before the Psychological and Neurological Association of Vienna, entitling my address "Encephalitis Lethargica." I gave the disease this name because the majority of the patients showed somnolence and disorder of the optic musculature, but I exhibited at the same demonstration patients with other symptoms and without drowsiness. I identified the disease with the mysterious "Nona" of 1890.[1] I also produced specimens showing the pathological anatomy, from which I proved that, despite the varying clinical picture, the condition was a disease-entity characterised by non-purulent non-hæmorrhagic inflammation of the grey matter: an inflammation consisting of a large number of small foci and involving the whole nervous system though chiefly localised in the grey matter of the mid-brain.; and one with no tendency to necrosis or softening. A few weeks later, working with Wiesner, I proved beyond controversy that the disease could be transmitted to monkeys and that it was therefore infectious. Since then epidemic encephalitis lethargica has been universally recognised as a disease-entity, and is described by many authorities under the shorter name of epidemic encephalitis.

A few months ago Cruchet published a short monograph entitled "Encéphalite épidémique—les 64 premières observations"[2] in which he claimed to *have been the first to discover the condition.* He asserted that he had described the first forty cases under the name of "encéphalomyélite subaiguë diffuse." This paper appeared in the *Bulletin* de la Société Médicale des Hôpitaux de Paris for April 27th, 1917. Since in any case it was published ten days after mine, I have the priority of date. Cruchet, however, claims that his work was published on April 1st, since that was the day on which he entrusted it to the post. This is against all custom, but even if it stands I can place my date of publication before that of Cruchet.

There is, therefore, no question about the priority of my paper. Moreover, I do not attach much importance to these dates, since I am satisfied that Dr. Cruchet could have known nothing about my work at the time he wrote his. The point I consider to be of far more importance, however, and which will at once be plain to every reader who studies Cruchet's cases in detail, is that the picture they show is in many respects quite different from that of epidemic encephalitis lethargica. If we select from his 64 cases the 40 which he saw before April, 1917, and discussed in his first paper, it is obvious that only a single one of them, to wit No. 45, represents a true encephalitis lethargica. In two other cases only—Nos. 16 and 29—there is a certain possibility of a differential diagnosis of encephalitis lethargica. All the remaining 37—or 39 if these two be included—show, by Cruchet's own description, no symptoms of epidemic encephalitis lethargica at all. They are all war-time psychoses, epilepsies, hemiplegias, or cases of myelitis or neuritis. None of the familiar symptom-complexes of encephalitis lethargica in its many forms plays a part in any of them and not one of them shows any symptoms of the mid-brain. If these 37 or 39 cases really manifest a disease-entity, as Cruchet says they do, it is a very different one from the encephalitis *lethargica described by me.* In the last few years we have come to recognise a variety of nervous diseases which are probably infectious, but are not encephalitis lethargica, such as Redlich's encephalitis cerebelli et pontis, Albrecht's encephalomyelitis migrans, Japanese encephalitis, and many varieties of acute multiple sclerosis. Sicard, the distinguished neurologist who died a short time ago, regarded epidemic singultus as distinct from encephalitis lethargica, and aptly suggested that these other varieties of encephalitis should be known by the name of para-encephalitis. If, therefore, Cruchet's cases really display a disease-entity—a hypothesis for which he provides no proof in his last monograph—his "encéphalite subaiguë diffuse" is at best one of these para-encephalitic conditions. It can hardly be assumed that 39 out of the 40 cases described by Cruchet as encephalitis lethargica showed *quite an atypical form.*

---

[1] Jahrbücher f. Psychiatrie, xxxix., 202.

[2] Doin et Cie, Paris.

Such anatomical details as Cruchet gives also make it quite obvious that his cases were not encephalitis lethargica at all. Only two of his cases were investigated anatomically; in one of these the examination was purely microscopical and revealed one or two large hæmorrhagic foci in the cerebellum, and none of the non-hæmorrhagic polio-encephalitis characteristic of my encephalitis lethargica. The other, No. 49, had presented throughout the clinical picture of Landry's *myelitis; microscopical examination* revealed a single focus of inflammation, as large as a pea, with a necrotic centre, in the white and grey substance of the medulla oblongata in the region of the hypoglossal nerve. The isolation and size of this focus, and particularly the central softening, show that it was produced by some other myelitic process and not by encephalitis lethargica. Cruchet, moreover, mentions especially that the cases he quotes showed no epidemic character.

It is clear, from all these *considerations, that the* question of priority does not arise; not only because my paper appeared ten days earlier than Cruchet's, but also because his encéphalomyélite subaiguë diffuse, if it is a disease entity at all, is quite distinct both clinically and anatomically from epidemic encephalitis lethargica.

A SIMPLE METHOD OF DEALING WITH CONGENITAL FISTULÆ.

By R. J. McNeill Love. M.B., M.S. Lond.,
F.R.C.S. Eng.,
ASSISTANT SURGEON, METROPOLITAN HOSPITAL, LONDON;
LATE SURGICAL FIRST ASSISTANT, LONDON HOSPITAL.

Congenital *fistulæ in* the neck, owing to continuous or intermittent discharge of glairy mucus, are a source of great annoyance to their possessors, particularly when adolescence is reached and a greater pride is taken in clothes and personal appearance. The two fistulæ for which treatment is most commonly sought are branchial and thyroglossal.

Branchial fistulæ are due to the non-closure of a cervical cleft, and are most commonly seen along the anterior border of the sterno-mastoid muscle near its lower end. They may extend upwards as high as the bifurcation of the common carotid artery. Very rarely they are completely patent, the inner end opening in the supratonsillar fossa.

Thyroglossal fistulæ are due to the non-obliteration of the thyroglossal duct, which extends from the foramen cæcum in the tongue to the isthmus of the thyroid gland. Authorities differ regarding its precise relationship to the hyoid bone, but from the surgeon's point of view the relationship is so intimate that if the fistula extends above the hyoid bone then the middle quarter of an inch of bone should be resected. The upper part of the thyroglossal duct occasionally remains patent, but this condition passes unnoticed during life, as the secretion merely mixes with the saliva.

The difficulty of complete removal of congenital fistulæ is largely due to the inability to ascertain their precise extent. This fact was well illustrated in one case which came under my notice in which five attempts had been made to remove a thyroglossal fistula. As a result the patient's neck was disfigured by an ugly contracted scar, from the lower end of which mucus still escaped. Further dissection with the removal of the centre of the hyoid bone and a wedge of the tongue muscle resulted in cure.

Attempts to inject opaque substances, with subsequent radiography, are not always successful, as the orifice of the fistula may be almost capillary in calibre, and the outlying portions of the fistula already contain mucus. Again, passage of a probe is uncertain, as constrictions in the fistula may hinder its progress.

A simple procedure which greatly facilitates removal consists in encircling the orifice of the fistula with a fine purse-string suture of horse-hair. This is inserted as close to the orifice as possible and tightened so as to close the opening. In a few days continued secretion begins to distend the fistula, converting it into a cyst. When sufficiently tense, the limits of the fistula are clearly definable, and accurate dissection and complete removal with a minimum amount of trauma are then comparatively easy.

Case 1.—Female, aged 22. Branchial fistula, 1 inch above sternum along anterior border of right sterno-mastoid. Injection of bismuth *paste and radiogram suggested that* the fistula was about ¼ inch in length and passed inwards. A purse-string suture was inserted, and three weeks later a firm cord-like swelling was easily palpable, passing inwards and downwards. Under local anæsthesia this was dissected out, the fistula being 1¼ inches in length and passing downwards and inwards under the deep cervical fascia. Section showed columnar epithelium.

Case 2.—Female, aged 12. Thyroglossal fistula. Seven days after purse-string closure, was distended, passing upwards and apparently attached to the hyoid bone. On dissection it was *found to be attached to the posterior* aspect of the bone, reaching as high as its upper border. The middle portion of the bone was removed. Section showed columnar epithelium with the remains of cilia.

Both wounds healed by first intention and have remained healed after a lapse of several months.

Centenary of Cheshire Mental Hospital.—The centenary of the Cheshire County Mental Hospital at Upton, Cheshire, was celebrated on July 2nd.

Fellowship of Medicine and Post-Graduate Medical Association.—The course in gastro-enterology, tentatively arranged for July 22nd to 26th, has been postponed and will be held at the Prince of Wales's Hospital, Tottenham, from Sept. 30th to Oct. 4th. There will be three courses in August: In urology, at the All Saints' Hospital, Vauxhall Bridge-road, occupying each afternoon from July 29th to August 24th; in diseases of children, at the Queen's Hospital for Children, Bethnal Green, occupying most of each day from August 12th to 21st; and in medicine, surgery, and the specialities at the Queen Mary's Hospital, Stratford, occupying the whole of each day in demonstrations, operations, and lectures in the various departments, from August 26th to Sept. 7th. Subjects of courses in September include diseases of the chest at the Brompton Hospital, from Sept. 9th to 14th; diseases of infants at the Infants Hospital, from Sept. 9th to 21st; psychological medicine at the Bethlem Hospital, Tuesday and Saturday mornings, from Sept. 10th to Oct. 5th; and medicine, surgery, and the specialties at the Westminster Hospital, from Sept. 10th to 28th. The following special courses have been arranged in addition to the list published for the year: evening course for the M.R.C.P. Lond., from Oct. 15th to Dec. 6th (Tuesdays and Fridays at 8.30 P.M.); and an all-day course in medicine, surgery, and the specialties at the Metropolitan Hospital, Kingsland-road, from Oct. 21st to Nov. 2nd. Syllabuses of special courses, together with information about the general course of work, may be had from the Secretary of the Fellowship of Medicine at 1, Wimpole-street, London, W. 1.

Medical Societies.

MEDICAL SOCIETY FOR THE STUDY OF VENEREAL DISEASES.

THE annual meeting of this Society was held in London on July 12th, with Dr. J. H. COUTTS, the President, in the chair. After the transaction of business, which included the re-election of the President, the discussion was resumed on Col. HARRISON'S paper, read at the last meeting,[1] on

EXPERIMENTAL WORK IN SYPHILIS AND ITS POSSIBLE BEARING ON MAN.

The PRESIDENT remarked that many of the conclusions which were drawn from the experimental work on animals were disconcerting to those treating the human being, and seemed contrary to preconceived ideas. The subject of immunity, both to tuberculosis and syphilis, was remarkably complex. It was hoped that this country would not be so behindhand as in the past in carrying out research on it. The United States were affording a valuable object-lesson in this respect, and to-night the Society was fortunate in the presence of Dr. Louise Pearce, of the Rockefeller Institute of Medical Research.

Dr. LOUISE PEARCE said she had read Col. Harrison's able review, and had been invited to give a short account of the work which had been carried out on syphilis by Dr. Wade Brown and herself, working entirely with the rabbit, in which animal the disease was found to be as characteristic as in the human. It was a chronic disease, and strains were used which were passed from rabbit to rabbit many times, being each time capable of imparting the disease. *It was non-lethal and was self-limited*, in that the manifestations eventually disappeared. The rabbit, however, remained infected as long as it lived, and the spirochæte could at all times be recovered from the lymph nodes. Two or three weeks after intratesticular inoculation one found the first clinical manifestations of the disease. In the third week a primary orchitis developed. After two or three more weeks that lesion regressed and almost healed. The second latent period was the fifth week. After a variable period of time—usually seven weeks—if one testicle had been inoculated, there was a metastatic orchitis, and, shortly afterwards, secondary lesions were found in the bones; after a further period the skin and mucous membranes were involved, and then the eyes. After three to four months the manifestations of disease had all practically healed except the residual lesions of the tunics, the epididymes, and sometimes the testes. The animal thus recovering could be proved to be a carrier only by inoculation of its tissue into another animal. The typical order or sequence of infection of tissues was: bone, skin, mucous membrane, eyes, though this was not invariable. If five animals were inoculated in the testes with a given dose of inoculum, one would be found to have severe syphilis, one very mild syphilis, and three disease of intermediate severity.

In work of this kind it was very important to use and have available a large number of animals. At the Rockefeller Institute a round was made of the patients every morning, just as in the human wards of a hospital. The strains of spirochæte used must be virulent—i.e., they must be able to induce manifestations of the disease; also there must be an appropriate adaptation of the rabbit's tissues; the soil must be suitable; and the dose must be adequate. The route of inoculation was likewise important. In the animals she used, the inoculations were intratesticular, scrotal and ocular. When no primary lesion was supposed to have occurred after intravenous injection she thought there were multiple primary lesions. So far as the work had gone, the characteristics of the host seemed to be relatively more important than the characteristics of the parasite, so far as the eventual outcome of the disease was concerned. The "host factor" included breed, sex, age, and general condition. The ordinary grey-brown rabbit gave the best results. The New Zealand red rabbit proved to be very resistant to the disease. If the animal was in poor health, the results of the experiment were not satisfactory. Environmental conditions were also very important; for instance, caging or a sedentary life had a marked influence on the manifestation. The animals were separately caged and fed on a standard diet. If inoculation was carried out within two or three days of the animal's arrival, the usual result was to get a more severe disease than if the animal were first kept three or four weeks—i.e., after it had become adapted to the sedentary life. Also the experimentally induced disease was much more severe in spring and autumn than at any other time. To further elucidate this point, sets of animals were placed in three kinds of rooms: an ordinary animal room, lighted by two windows of ordinary lead glass facing south; a room strongly illuminated by electricity the whole time; a room continuously dark. The animals were detained there during the four months of the experiment. It was found that the disease manifestations—i.e., the efficacy of the reaction—increased with the amount of light and the constancy of exposure to it. Animals in the constantly dark room showed deterioration, particularly changes in the thyroid, thymus and parathyroid glands. In some of the rabbits a complete, in others a partial thyroidectomy was performed, and the inoculation of the spirochæte which followed this gave such severe syphilis as the speaker had seldom seen. It seemed that the resistance to the disease was subject to the same influences as those concerned in regulating growth and maintaining the general metabolic activity. Dr. Pearce's latest inquiry concerned the effects of dosage and the various routes of inoculation. If one simply dropped a suspension of 0·2 c.cm. inoculum into the eye, it was diluted, and one did not know how many spirochætes remained adherent to the surface—probably very few. In some previous work she noted that when this route was chosen the disease was very mild, especially in comparison with the following intratesticular inoculation, the material in the latter case being forcibly injected. Metastatic orchitis was, strictly speaking, a secondary lesion, but the conditions of growth were so different that she and her colleagues made a separate division for it. All the animals experimented with developed generalised lesions. With intratesticular inoculations the dose was enormous in comparison with the ordinary dose received by the human beings, and so the primary lesion was an enormous one. The result of that, presumably, was a rise in immunity, or an increase in the efficiency of the immune reaction. If both testicles were inoculated—i.e., if a double lesion were produced, the primary syphilitic lesion was doubled, but there were not so many secondary lesions.

Another set of experiments, said Dr. Pearce, was also very instructive—namely, concerning double or concomitant infections. By chance, she had found that an animal sent from Europe supposed to contain certain strains of *Spirochæta pallida*, also carried a vaccine virus. Injecting the latter into an animal at the same time as the spirochæte resulted in what could only be called malignant syphilis. If intratesticular syphilis was inoculated into a vaccine-immune animal, the syphilis was mild. If into the same testicle vaccine virus and syphilis were inoculated, again the syphilis was mild. The reason, probably, was that the destruction of tissue had provided a poor medium for the growth and distribution of the spirochætes. The influence of one infection on another, well recognised in connexion especially with children's diseases, she did not think had been sufficiently realised in this work. Blood examinations showed a tremendous increase in mononuclear cells in the circulating blood at the time of the occurrence of the metastatic orchitis and the secondary lesions. Similar changes were seen in association with virus disease, and also in malignant tumours of rabbits.

---

[1] See THE LANCET, 1929, i., 1248.

In conclusion, Dr. Pearce said it was necessary to observe considerable caution in applying results obtained in animal work to the human being. The disease presented many points of similarity in the two cases, but also many differences. She also insisted that before results of work were given out to the world, considerable numbers of animals should have been used, to avoid all accidental error.

The PRESIDENT spoke of the great value of the research carried on by Dr. Pearce, which required much patience, as weeks of observation were sometimes needed in order to establish one apparently small fact.

Mr. DAVID LEES agreed with Dr. Pearce about the caution needed before applying to man the results of animal experiment on this subject. Some said that better results from the treatment of syphilis would be obtained by waiting until about the eightieth day after the infection was acquired before initiating salvarsan therapy.

Dr. H. M. HANSCHELL asked whether Dr. Pearce found, in these experiments, lesions in the walls of the arteries and other vessels.

Dr. PEARCE replied that practically no lesions of the vessels were to be found with the exception of those of the heart, and only very few there. Many more granulomatous lesions were found if the animals were killed at the beginning of the secondary period. The lesions in the rabbit seemed to be peripheral rather than central.

SOCIETY FOR THE STUDY OF INEBRIETY.

AT a meeting of this Society held on July 9th, Mr. W. MCADAM ECCLES took the chair and delivered his presidential address, which was entitled

Some Gaps in the Scientific Study of Inebriety.

Much, he said, remained to be discovered about the effect of varying percentages of circulating ethylic alcohol upon the cellular contents of the blood and upon the blood-plasma itself. Arteriosclerosis was now reported as one of the principal causes of death; had alcohol any effect on the delicate cells of the arterial walls, and was arteriosclerosis more common in immoderate than in moderate drinkers of alcohol? Was the low expected mortality of the total abstainer due to freedom from arteriosclerosis? Alcohol in large doses caused peripheral neuritis, and it might be that much lower dilutions might affect the more delicate nerve mechanisms of the blood-vessels. This might perhaps be a cause of the stigmata seen on the cheeks of those who indulged freely in alcohol. Investigation was required to establish whether alcohol circulating in the blood affected the muscular tissue of the heart as well as the endocardium, and to discover the cause of fatty degeneration of the heart, which occurred even in moderate drinkers. Modern text-books gave no explanation of the nature of delirium tremens. If it were due to circulating ethylic alcohol, the practice of tapering alcohol in its treatment was illogical. The possibility that it might be due to another constituent of the beverage, or to some toxin produced in the body, should be investigated. Work was also necessary on the effects of alcohol on urine excretion, and the length of time taken by the alcohol from one glass of champagne to appear in the urine and to disappear from it; the results might be useful in establishing tests for drunkenness in motorists.

Sir WILLIAM WILLCOX then opened a discussion on the

Toxic Effects of Methylated Spirits and Impure Forms of Alcohol.

In 1858, he said, the Government had felt that alcohol used in art, commerce, and industry should not pay a tax, and for this reason methylated spirit, or ethyl-alcohol containing 10 per cent. of wood naphtha, had been introduced. During the war the authorities had found that people could drink this spirit, and a mixture was produced containing 9·5 per cent. of wood naphtha, 0·5 per cent. of pyridine, and 0·375 per cent. of paraffin, together with some colouring matter. The methylated spirit of to-day was poisonous both internally and externally. Its use in industry was hampered by the substances it contained, and another spirit had therefore been introduced consisting of 90 per cent. of ethyl-alcohol mixed with 5 per cent. only of wood naphtha. This industrial spirit was sold under strict safeguards. Surgical spirit was industrial spirit to which had been added 2½ per cent. of castor oil and 1 per cent. of boric acid, to make it still more unpalatable.

Many cases of illness due to methylated spirit drinking had been observed. In America 2000 deaths from this cause had been recorded in 1926. The evil had been prevalent in Scotland in 1922, and a convention of the Royal Burghs had met and passed stringent regulations to prevent it. Isolated cases had occurred in this country, but the speaker had never met one in which the patient had taken the spirit sold nowadays. Methylated spirit produced much the same symptoms as alcohol. The most dangerous of the effects of the methyl-alcohol, or wood naphtha, was blindness, but the speaker did not know that any case had been recorded in this country. In the great eye hospitals, however, about 5 per cent. of the cases of optic atrophy were due to undiscovered causes, and perhaps methyl-alcohol had not been sufficiently considered as a possible factor. A departmental committee which had sat in 1926 had decided that it would not be in the general interests of the community to label methylated spirit as poison. In the United States, however, every package containing less than five gallons was marked with a skull and cross-bones, and the inscription:

> "Completely de-natured alcohol is a violent poison. It cannot be applied externally to human or animal tissues without serious injurious result. It cannot be taken internally without inducing blindness and general physical decay, ultimately resulting in death."

This summed up the whole situation: it was the impure forms of alcohol which were dangerous to life and sight.

Methyl-alcohol was slower than ethyl-alcohol in its action, and symptoms might not appear for several hours.[1] It produced gastric irritation, with abdominal pain and vomiting; intense headache; drowsiness and coma, which might last for three or four days. The fatal dose was 1–2 ounces. It had a selective action on the optic nerve, so that the patient who took a large dose, whether it made him drunk or not, usually became blind. Partial recovery might take place after a few days, but was succeeded by permanent loss of sight or a central scotoma. Methyl-alcohol was excreted very slowly; the breath would smell of it for over a week, and even after that time 50 per cent. of the poison would remain unoxydised in the body. Its oxidisation produced formic acid, which might be the cause of the optic neuritis. Methyl-alcohol had been used in many countries as a substitute for ethyl-alcohol, and beverages containing it were most dangerous poisons, for they were taken in the same quantities as if they contained ethyl-alcohol. It was sometimes sold in America as Columbian, Colonial, or Eagle spirit, and essences of ginger and peppermint, bay rum and bitters made with it had caused numerous deaths some years ago. It had also been used to adulterate whisky, brandy, sherry, rum, and cider. Serious epidemics of poisoning had resulted in Germany from brandy containing two-thirds of methyl- to one-third of ethyl-alcohol; out of 113 men who had drunk this mixture, 56 had died and 42 had become blind. Roumania had also suffered recently from similar epidemics due to the use of industrial alcohol. These examples proved that the evil was not confined to countries where alcoholic beverages were prohibited.

Isopropyl alcohol, or C_3H_7OH, had the same value as ethyl-alcohol in forming the basis of tinctures. It was not taxed, because it did not produce the pleasurable effect of ethyl-alcohol. It was twice as poisonous and induced lethargy, headache, and epigastric pain. Tolerance was established, and the permanent effects were no more harmful than those of ethyl spirit. Allyl alcohol, or $C_5H_{11}OH$, had as its principal constituent, fusel oil, a late product of yeast distillation; it was five times as poisonous as ethyl-alcohol. Contrary to a widespread belief, however, it was not responsible for the effects of the ingestion of bad spirits, as it was present only in minute quantities. The speaker enumerated some of the commoner alcohols and described their formation from hydrocarbons by the substitution of a hydroxyl for an oxygen group.

The PRESIDENT remarked that some three hundred varieties of alcohol were known to chemists; all the forms mentioned by the speaker were pure, and he questioned his use of the term "impure forms of alcohol."

Dr. COURTENAY WEEKS stated that investigations by the United States Government had proved that many of the deaths from spirit drinking were not due to methyl-alcohol, but to the effects of unusually large quantities of ethylic alcohol. Whisky in America might be above proof—i.e., contain more than 57 per cent. of ethyl spirit—and its consumers were liable to treat it as though it contained less than half that proportion. Many deaths reported as due to methylated spirit had occurred before prohibition, and victims of this poison were usually persons who were already vitiated by ethyl-alcohol. Dipsomaniacs would drink all kinds of irritant substances indiscriminately; he quoted a case where one had tried to make a beverage in a saucepan with paint scraped from a door.

Sister EMILY ISABEL mentioned two cases of methylated spirit addiction under her care. One was in a middle-aged woman, who was also a heavy drinker of other forms of alcohol, and had been taking impure methylated spirits for two years because of their cheapness; she was going blind. The other patient had used methylated spirit because it was easier to hide from her husband; her sight was not affected.

Mrs. M. S. DALTON agreed that the cheapness of methylated spirit was an attraction.

Mr. L. A. SENN asked if the Colonial or India Offices analysed the gin shipped from Holland to West Africa, or the foreign brandy imported by India and the Colonies in hundreds of thousands of gallons every year. These spirits must have a very deteriorating effect.

Sir ARTHUR NEWSHOLME remarked that the increased mortality from various causes shown in the statistics from time to time were largely due to "fashions" in nomenclature. The present fashion was arteriosclerosis. The high reported mortality from methylated spirit drinking in America might also be due to a passing phase of public interest in this cause.

Dr. F. W. WILLWAY pleaded for some effort to correct the erroneous idea, fostered by systematic propaganda in the daily press, that prohibition was responsible for indulgence in impure forms of alcohol. All alcohols were poisonous, and it would be of no advantage to remove restrictions on the sale of ethyl-alcohol.

Sir WILLIAM WILLCOX, in reply, agreed that the number of different alcohols was probably infinite. Much of the harmful effect of methylated spirit poisoning was, of course, due to its ethyl-alcohol content. He mentioned the case of a female patient who had been rich enough to afford the finest alcoholic beverages but had preferred methylated spirit—of the pre-war kind—probably because its effects were more intense and prolonged. She had been very neurotic. Another very tragic case was that of a young man who, after one drink of adulterated whisky in America, had developed central scotoma and died of cerebral degeneration.

Reviews and Notices of Books.

UNIVERSITY COLLEGE, LONDON, 1826–1926.

By H. HALE BELLOT, M.A., Reader in Modern History in the University of Manchester. London: University of London Press, Ltd. 1929. With nine statistical charts and other illustrations. Pp. 404. 25s.

IT is always of interest and oft-times of importance to trace the way in which great institutions come into being. In cases where the history is ancient, when we endeavour to follow it far back we do not often get behind the stage of firm establishment, and we are able to learn little or nothing of the actual origins; but in institutions of more recent formation we have an opportunity of learning the mode of their birth, and we can trace development year by year until the position which they occupy to-day is reached. So it is with the teaching body which we now call the University College, London, and its offspring the University of London itself.

Sir Thomas Gresham's foundation in the middle of the sixteenth century introduced the idea of a University of London 200 years before the inception of the present University, but from one cause or another it had never borne fruit. It was not until the year 1820 that a real beginning was made, when Thomas Campbell, the brilliant erratic poet, went to Bonn, and there was struck by the mutual tolerance in University circles of protestants and catholics and by the liberal treatment accorded to the Jews; at once the desire for a University for London arose in his mind, which should admit to its privileges and opportunities all who wished to learn without distinction of creed. There can be no doubt that it was Campbell's promulgation of this sentiment that led ultimately to the establishment of the University of London. The older universities had done much splendid work and were doing it; they had changed also in response to the changes in the life and thought of the country, but the work they were doing, excellent though it was, did not fulfil all the needs of the time. The enormous advances in physical science, the changes in many branches of exact knowledge, and the development of new classes in society whose interests differed in many ways from those of the dominating sections of the previous century—all these things had led to a widespread feeling that there was room for drastic alteration in the mode of training those who had to take part in the business of life in every field of activity. Science was not receiving the place in education which its ever-increasing importance in manufactures demanded. But—and it was, of course, the fact of prime importance—in the older universities even that measure of science which was taught, and which was capable of practical application, was not available to that large portion of the population which did not belong to the Established Church. In this respect there were indeed slight differences between the attitudes of Oxford and Cambridge, but at neither University could a degree be obtained by any nonconformist. Thus there was a large body of all denominations anxious to have systematic teaching in many branches of modern learning who were unable in this country to get any university training at all. It was not that in Great Britain there was any lack of modern thought; in Scotland especially much had been done during the latter half of the eighteenth century to advance the cause of modern learning; but the fact remained that the whole country was not benefiting as it should have done from the accumulating stores of knowledge, and this at a time of great material development.

Exactly at this place a great factor in the demand for a modern university in London was furnished by the position of medical education. It was seen to be unreasonable that a London student of medicine should be unable to obtain a degree in London, but be forced to go to Oxford or Cambridge, or to proceed to other divisions of the Kingdom or abroad. Moreover, though there was an enormous amount of clinical instruction available in London, all the systematic teaching was on the whole ill-organised; for the large number of medical students in London the need for a regular and complete course of medical teaching in London was urgent, and this made obvious the great desirability of the establishment of a university medical faculty in the metropolis. To Campbell must be given the credit of bringing to a head the recognition of this need; the original idea was his, and credit is often given to others which, in part at least, belonged to him. But a large number of progressive and highly educated men resident in London soon came to take part in the attempt to form a metropolitan university, and Campbell was soon joined by, among others, Brougham, Bentham, Grote, Mill, Tooke, Macaulay, Birkbeck, and Goldsmid, who may be taken as typical of those who shared in the work. Ultimately it was resolved to start a joint stock company, and under a deed of settlement it was arranged to raise a capital of not less than £150,000. Sufficient money was received, not without delays and disappointments, to justify the laying of the foundation-stone of University College under the title "London University," and this was done on April 30th, 1827.

Then came the task of appointing the professors. The new Council of the College wished to choose men of high standing, but the fact that the emoluments of the professors had to depend mainly on the fees of the students, while the students had not yet materialised, limited the number of applicants, and many difficulties arose. Of the professors appointed some in nearly every department resigned after a short tenure of office, and the lack of sufficient capital increased greatly the responsibilities of the Council. Of all the departments during the first few years of the life of University College, the most successful by far was that of medicine. In the first session there were 183 medical students, in 1831 there were 252, and in 1834 the number had risen to 390, when the success of the new institution led naturally to imitation by other metropolitan medical schools and the rate of increase fell off. At first the medical students of University College had to seek their clinical knowledge where they could obtain it, but University College Hospital was opened in 1834, and this disability was removed. But Mr. Hale Bellot brings out clearly in his book the anxious time which the College had before it for many years. The establishment of King's College, London, detached many who would otherwise have been students. The Law Society and the Inns of Court established courses of lectures on the various branches of legal study, and this reduced the number of legal students, and the need of a charter to give power to confer degrees was a serious drawback. It was exactly this proposal on the part of the Council that was the cause of the greatest opposition; this came particularly from Oxford and Cambridge and the Royal College of Surgeons of England, and it seems, from physicians and surgeons of the medical schools of London other than the school of University College Hospital. But towards the latter half of 1836 the Government of the day took a hand. Two charters were drafted, by one of which the body hitherto called London University was incorporated as University College, London, while by the other charter an entirely new body was created, to be styled the University of London with the full powers of a university. Thus the long struggle was ended in what was probably the best settlement, despite subsequent history.

umber of its students, who went to other educational bodies, which were now granting increased facilities. It was not until the sixties that the fortunes of the College were placed upon a firm basis, but by that time it had become generally recognised that it had achieved and was achieving famous deeds in enlarging the sphere of learning, in removing obstacles which hindered the entry of promising students, and in turning out graduates fit to hold great national positions. Since that time the progress has been continuous. In many departments of learning the College has been a leader, and from its walls many professors have gone out as missionaries of learning to other seats of education. During the hundred years that have passed since its foundation it has done perhaps more than its famous founders expected, while it is entering on its second century stronger than it has ever been.

Mr. Hale Bellot has written a clear and interesting account of the birth and growth of University College, London, and we congratulate him on a literary performance which must have called for an infinitude of labour, as the multiplicity of references and the elaborate statistical tables show, while proving the trouble he has been at to secure accuracy. May we, from a personal point of view, mention one thing? On page 395 it is stated that in 1888 a house at Longcross was left to University College for use as a convalescent home; the house was bequeathed to the College in 1886 by James Wakley, the editor of THE LANCET from 1862 until his death in the year of the bequest.

THE PHYSICS OF X RAY THERAPY.

By W. V. MAYNEORD, M.Sc. London: J. and A. Churchill. 1929. Pp. 177. 10*s.* 6*d.*

THE essential messages of this book concern practical therapeutic X ray measurement, and are introduced by arguments drawn from physics which imply considerable mathematical proficiency; the *methods of X ray measurements are discussed*, and then the chief results of such measurements are detailed with the effects of varying conditions of irradiation in practice. The problem of the radiologist, viewed from the physical standpoint, is to deliver a certain dose of X rays at a determined depth below the surface, while observing, as far as may be, the distribution of X radiation within a mass of tissue. A clear résumé of the important factors affecting the choice of therapeutic conditions is given, and the small book closes with an analysis of the physical principles underlying the construction of the apparatus used in X ray therapy. The author acknowledges in the preface assistance from Kaye's "X Rays," Grossmann's "Physikalische und technische Grundlagen der Röntgentherapie," and Compton's "X Rays and Electrons," and to the first two authors he is indebted for permission to use data from their respective treatises. As an account of some of the physics of X ray therapy the book is of distinct value, and displays its author's intimate knowledge of the subject.

TROPICAL DISEASES.

The Diagnosis and Treatment of Tropical Diseases. Fifth edition. By E. R. STITT, Ph.G., M.D., Rear-Admiral, Medical Corps, U.S. Navy; Graduate, London School of Tropical Medicine. London: H. K. Lewis and Co., Ltd. 1929. Pp. 918. 31*s.* 6*d.*

THOSE who have profited from the earlier editions of this comprehensive book will welcome its development into an imposing octavo volume, fully illustrated with no less than 249 figures. It has now taken a high place amongst the standard works on this subject in any language containing an immense amount of information on many subjects which are not even mentioned in other text-books. The opening chapters on malaria are admirable; the sensible views expressed upon the subject of quinine prophylaxis are backed by an array of facts and figures of great use to the malariologist. In the treatment of sleeping sickness emphasis is laid upon the action of etharsanol and proparsonol, two new arsenical derivatives prepared by W. K. Stratman-Thomas and A. S. Loevenhart. Finality in nomenclature of typical parasites has not been attained, and we have not previously seen the generic term *Borrelia* applied to the blood spirochætes; *Wucheria bancrofti* replaces the time-honoured *Filaria bancrofti*. It must be admitted that the frequent changes in the nomenclature of parasites are a source of confusion to the student and of despair to the teacher, and we trust it will soon become standardised.

In the treatment of relapsing fever the contra-indications for salvarsan therapy are emphasised; these apply equally well to the treatment of syphilis. The discussion upon the nature, chemistry, and therapeutic utility of vitamins is on a broad basis not confined to tropical diseases, and the same may be said of the excellent index of clinical diagnosis. The hygienist and epidemiologist will glean much information of value, not, as far as we are aware, obtainable elsewhere, on anatomical and physiological normals and on the physiology of tropical residence.

So far very good, but the book is so packed with scientific data that practical points in treatment have suffered. This section is not developed in sufficient detail. While most of the illustrations are excellent, future editions would be much enhanced by the inclusion of coloured plates, especially in the section on malaria.

Exotische Krankheiten. Ein Lehrbuch für die Praxis. Second edition. By Prof. Dr. MARTIN MAYER. (From the Institut für Schiffs- und Tropenkrankheiten.) Berlin: Julius Springer. 1929. Pp. 368. M.39.

ALTHOUGH some five years of fertile work have elapsed since the publication of the first edition of this practical handbook, it has been found possible to incorporate the new information without adding largely to its bulk. Zoological and entomological data are supplied with reference to each disease, and no attempt is made to deal with protozoology and helminthology as separate entities. A hæmatological section forms a useful addition. The descriptions are adequate but very brief. The text illustrations, especially those in colour, deserve especial praise. This book is likely to be popular among students of tropical medicine who know German, though the price is high for a manual of this kind.

THE PRACTICE OF PERIODONTIA.

By SIDNEY SORRIN, D.D.S., and S. C. MILLER, D.D.S. New York: The Macmillan Company. Pp. 160. 15*s*.

IN the introductory note by J. McCall and P. Stillman this book is stated to be "a milestone of progress in the control of periodontal disease by the dental profession." So laudatory a statement raises hopes which are damped when we find that the book is an exposition of the thesis that pyorrhœa is chiefly caused by "traumatic occlusion" and that the methods of treatment described are based throughout on the assumption that this hypothesis is correct. The chief protagonists of this particular theory are McCall and Stillman, and while it is not unnatural for them to regard with special favour such enthusiastic disciples as Sorrin and Miller, more impartial testimony to the outstanding merits of the book is still to seek. It is generally admitted that gross deviations from what is usually termed normal occlusion put an excessive stress on the teeth which may so injure the supporting tissues that they become unable to resist infection. There is much clinical observation to support this view, which is by no means a new one. But the advocates of traumatic occlusion as the chief ætiological factor in pyorrhœa go far beyond this. They postulate a rigid standard of arrangement of the teeth as the normal one and every deviation from this, however slight, as being essentially pathological. Furthermore, the existence of pyorrhœa in a mouth is regarded as an implication that the occlusion is traumatic and therefore must be corrected by grinding the teeth or using some prosthetic or other forms of restoration to the "normal." In the chapter labelled physiology it is pointed out, no doubt correctly, that the grooves on the crowns of teeth act as spill-ways which deflect food from the septal tissues and protect the latter from injury. Few would agree that the function of these grooves is so vital that teeth worn flat by attrition should be artificially grooved. The difficulty of accepting their views is that occlusion so far from being fixed, varies throughout life in proportion to the normal wear of the teeth, which brings about a progressive series of modifications in the relationships of the upper and lower teeth. In prehistoric man, among primitive peoples, and even in some individuals of the highly civilised races, attrition sufficient to obliterate the cusps and grooves is a normal feature of adult life. It is a familiar fact that persons whose teeth show well-marked attrition have healthy mouths. Attrition is evidence of vigorous mastication combined with the use of a coarse, detergent diet; and we fail to see any adequate reason for the artificial rejuvenation of the teeth here advocated. Much of the treatment recommended in the book is sound, for it embodies measures practised successfully by dentists all the world over long before the theory of traumatic occlusion was propounded. Those who are prepared to winnow the grain from the chaff will find useful and interesting hints in this book, but its value to the general medical reader is vitiated by its insistence on developing a hypothesis which is fantastic rather than scientific.

ANATOMY AND THE PROBLEM OF BEHAVIOUR.

By G. E. COGHILL, Wistar Institute of Anatomy and Biology, Philadelphia. Lectures delivered at University College, London. London: Cambridge University Press. 1929. Pp. 113. 7*s*. 6*d*.

THESE lectures concern the study of the growth of behaviour in the light of the development of the nervous system. The work on which they are based was carried out almost exclusively on amblystoma, which afforded excellent material for this kind of study. While psychologists view the problem of behaviour from the more or less philosophical angle, it is rather the objective attitude that has prompted the line of research in this investigation. Dr. Coghill has observed the gradual unfolding of amblystoma in order to follow the changes in the structure of the nervous system pari passu with the appearance and acquirement of full function of the limbs. The study of the relation between movements of the limbs and those of the trunk is essentially the study of one of the most important activities of the organism, that of locomotion. How far correspondence of behaviour to neural structure satisfies all the peculiarities of organic life is open to grave doubt, but there are good methodological reasons for supposing correspondence between neural events or patterns and behaviour. The discovery of the Rohan Beard cells linking up proprioceptive with exteroceptive mechanisms helps to explain that strange integrity of inner and outer events which make up the associations in the higher or psychic life of the organism. The demonstration of the growth potentiality of this system does something to check the apparently victorious march of behaviourism into neurological territory and thence into psychology. The conception of continued growth in this Rohan Beard system allows for the possibility "that such a progressive differentiation of sensitivity may be the essential constitution of the conditioning process." Hence the study of these growth potentials assigns a limit to crude behaviourism, and the impulse of growth which Dr. Coghill's researches have led him to invoke, becomes inventor and operator to the organism.

JOURNALS.

AMERICAN REVIEW OF TUBERCULOSIS, Vol. XIX. (Nos. 4–6).—*April.*—Two studies on Pulmonary Acoustics are contributed by P. F. Metildi and R. S. Lyman, and R. R. Hannon and R. S. Lyman.—Stephen J. Maher illustrates an article on Some Sources of Acid-Fast Bacilli with a series of coloured plates. Acid-fasts are forms of ordinary bacteria which have developed waxy capsules to resist an unfavourable environment. They frequently accompany cancerous growths. These are distinguished from tubercle bacilli by their action in curdling and reddening litmus milk.—Frederick L. Hoffman writes on Cancer of the Lungs. The increase in this form of malignant disease is real and is probably connected with atmospheric pollution due to modern development of road transport. Neither smoking, effects of gas poisoning nor the influenza pandemic appear to have influenced the spread of the disease nor has any direct connexion between pulmonary tuberculosis and malignant lung disease been established.—Everett K. Geer, F. F. Callahan, and D. Greth Gardiner describe their experience in the use of Iodised Oil in Pulmonary Tuberculosis. The supraglottic method is recommended in order to avoid trauma to mucous membrane in frequent contact with tubercle bacilli. Injections are of value in defining fistula tracts, outlining tuberculous empyema cavities, determining the pulmonary condition when thoracoplasty is under consideration and in revealing slight degrees of bronchiectasis, as the source of unexplained hæmoptysis.

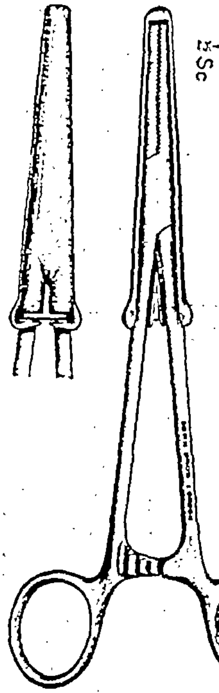
May.—Edgar Sydenstricker discusses the Trend of Tuberculosis Mortality in Rural and Urban Areas. That of the former was essentially identical with that of the latter during the period 1900–15, but since the world war the net effect of the interplay of various factors upon the tuberculosis death-rate has been to favour a somewhat greater decline in cities than in country districts.—Ralph R. Mellon and Elizabeth L. Jost describe experiments on the filtrability of the granular phase of the tubercle bacillus.—A. Levinson contributes a Study of Pulmonary Tuberculosis in Children. Cases may be classified as (1) generalised miliary tuberculosis, (2) acute tuberculous pneumonia, and (3) subacute or chronic pulmonary disease. While most of the cases in the last group are of the adult type, reference is also made to chronic tuberculous broncho-pneumonia in infancy and to the so-called epituberculosis of Eliasberg and Neuland. The tuberculin test was negative in all cases of miliary tuberculosis.—Richard H. Miller and William M. Shedden deprecate the modern tendency to exclude operative measures from the treatment of tuberculous cervical adenitis. While recognising the value of hygiene, heliotherapy and X rays they consider that tuberculous lymph glands constitute foci from which disease may spread at any time and prove a source of grave danger. Radical surgical operation is the method of choice in a considerable number of cases in both adults and children.

June.—A. Calmette and Harry Plotz contribute a leading article on Preventive Inoculation against Tuberculosis with the Bacillus Calmette-Guérin in which they vigorously controvert the opinion that the B.C.G. vaccine is dangerous.—Adolph L. Gallant describes the results of the treatment of syphilis in tuberculous patients. A positive Wassermann reaction was obtained in 21 per cent. of hospital patients suffering from pulmonary tuberculosis. Treatment of the syphilis resulted in marked amelioration of the symptoms of tuberculosis, and a significant reduction in the death-rate of the treated cases. In the presence of tuberculosis the dose of arsenicals should be reduced to half or one-third of the usual dose.—Benjamin Goldberg gives an account of the Chicago antituberculosis scheme. The most noteworthy regulation is one which makes it illegal for a child to share the home of a consumptive.—Theses by J. Dwight Davis and Maude L. Lindsey are concerned with obliterative changes of the pulmonary lymph vessels in tuberculosis and reactions of the subcutaneous connective tissue to experimental tuberculosis in the guinea-pig.

New Inventions.

APPENDIX SHIELD.

THE details of technique in the removal of the appendix, particularly the unperforated or "clean" appendix, vary considerably in the hands of different surgeons. The majority of surgeons prefer to insert the purse-string before dividing and removing the appendix, thereby reducing the chance of contamination of the peritoneal cavity to a minimum. Others make a practice of removing the appendix before inserting the purse-string; this makes matters more simple since the offending organ has not to be held up out of the way, but it has the grave disadvantage that it is impossible to be sure that the suture will not fall across the appendix stump and become contaminated. This danger can be obviated by fitting a shield or sheath over the blades of the Mayo-Ochsner forceps (see figure), grasping the stump of the appendix immediately the latter has been removed. Rowlands and Turner state that it is unnecessary to ligature the stump of the appendix provided it be crushed by a strong forceps for some moments before being covered over by the purse-string. The steps of the operation would then be as follows: The meso-appendix is ligatured and divided right down to the base of the appendix. The appendix is then grasped at its base by a Mayo-Ochsner forceps which is closed tightly. A second forceps is placed on the distal side of the first and as near to it as possible. The two forceps are then laid side by side on a piece of gauze and the appendix divided between them, close to the first forceps. The appendix is removed, the piece of gauze thrown away, and the stump of the appendix lightly touched with a swab which is thereupon thrown away. The appendix shield is now clipped over the blades of the Mayo-Ochsner forceps on the appendix stump. The purse-string suture is inserted, the shield and forceps removed and laid aside, and the operation concluded in the usual way. If for any reason the base of the appendix is divided before the meso-appendix, two shields may be used.



The shield is made by Messrs. Down Bros., Ltd., 21 and 23, St. Thomas-street, London, S.E.

Derby. A. ERNEST SAWDAY, F.R.C.S. Edin.

REBUILDING OF ST. BARTHOLOMEW'S HOSPITAL.—Lord Stanmore, the treasurer, states that the hospital can no longer meet the demands upon it, and that it must be enlarged, modernised, and partly rebuilt. The present wards were built nearly 200 years ago, and it is intended to launch an appeal for money in the early autumn.

THE LANCET.

LONDON: SATURDAY, JULY 20, 1929.

THE MENTALLY DEFECTIVE ADULT.

THE missing section of the report of the Mental Deficiency Committee has now appeared.[1] It will be remembered that Part III. of the Special Committee's report dealing with the adult defective was ready for publication when the rest of the report appeared in April,[2] but was held over for consideration by the Board of Control and the Ministry of Health. Conjecture had it that the delayed section of the report was too strong meat for the populace on the eve of a general election, or alternatively that it contained proposals for the sterilisation of the adult defective of a kind too drastic for promulgation at such a time. As we had good reason to surmise,[3] neither conjecture is realised in the report before us. Far from providing an easy solution of the social problem of mental defect, the Committee believe that the legal sanction of sterilisation would simply enhance the difficulty of bringing defectives within the scope of existing measures for control. We print *on another page* the few well-considered remarks in which the Committee convey this result of their investigation. The real thrill is contained not in this part of the report, but in the survey made by Dr. E. O. LEWIS and his assistants which appeared in April. This was the discovery that there are in this country some two and a half to three times as many defectives as are known to or being dealt with by the proper authorities. Their estimates were made by applying the figures of a local survey, with appropriate corrections, to the country as a whole. The resulting total was twice as high as that of the Royal Commission of 1906, and no doubt much of the excess is due to better ascertainment. There are now more welfare agencies of all kinds than there were, and with the rising standard of living the defective becomes more obvious. Mental defectives are finding more and more difficulty in getting work owing to the enforcement of trade-union standards, of workmen's compensation, of employers' liability, and of health insurance, obligations which make the employer more chary of taking on a defective individual. Thrown out of the labour market they come on the poor-law, and so into public notice. What real increase there may be is more marked in the country areas; the better and more energetic stock forsake the isolated villages, leaving behind a poorer stock to breed from. More inquiry is desirable in order to ascertain whether *this holds good generally.*

Having now answered to the best of their ability the two questions: How many defective persons are there, and what is the best thing to do with them? the Committee propose a third and very pertinent question: Are there any means of lessening the burden of mental defect? For this purpose they distinguish between primary and secondary amentia. The latter presents the simpler problem. Secondary amentia is usually of a low grade and is distributed with some uniformity throughout all social classes. Few secondary aments are likely to mate; girls, it is true, might be exposed to some danger if not cared for, but so far as is known secondary amentia is non-heritable. Moreover with improved midwifery, with the increase in antenatal and V.D. centres, and with the growth of infant welfare and school clinics most of the causes of secondary amentia are being dealt with. Primary amentia, on the other hand, occurs as a family and group problem; it is unevenly distributed in the population, the majority of the cases coming from the lowest tenth in the social and cultural scale. Part of the incidence depends on the germinal variation which occurs in all classes, a variation which is as likely to be in both directions as one only. Genius and defect may be found in the same family; as is well known, the Jewish race provides both much genius and much defect. If this is so, sterilisation would be liable to remove the assets as well as the liabilities of the race. In the main, however, primary amentia is an end-product of continuous poor breeding and deterioration of stocks. Relatively few are the children of *certifiable defectives*, many come from poor stocks in which there are all forms of social inefficients. In part it may be a cultural problem, for as culture rises, and with it the standard of living, fewer are willing to produce children for whom they can provide nothing. Cultural rise, moreover, seems to some extent to sublimate the sex instinct, and, as education penetrates, the birth-rate of the several classes will tend to approximate.

In education, then, the Committee see the chief hope of betterment. Of the effect of sterilisation on any particular group too little is yet known, while there is the risk of diverting public opinion from providing the needful institutions, for sterilisation does not render its object stable, employable, or amenable. Many, too, would hesitate to notify or certify the defective if his act might lead to a maiming operation. The greatest thing of all is to catch the defective young, to train him manually and in character, and to introduce him gradually to the world under efficient supervision. Much relief is given to defectives under the poor-law, but many who are now sent to institutions could remain at home if some small additional support were available. The Committee would make it legal to pay sums for maintenance of defectives under supervision, and would simplify the rules of guardianship which at present are so minatory as to frighten off the relatives. Though the distinction between mental deficiency and insanity may be useful in administration, both have environmental stresses especially in early life which need study. Out-patient and guidance clinics may do much to check the individual causes of degeneration. As all these things need correlating the Committee suggest that the time is coming, if it has not already come, to appoint a medical officer of mental health to survey all preventive measures from the mental standpoint as does the medical officer of health from the physical. Whether he should be attached to the health service, or to a separate mental service, is left open. Logically he would stand to the superintendents of mental hospitals or certified institutions in the same relation as the medical officer of health to the superintendents of sanatoriums or fever hospitals—and under the new régime of general hospitals. His task would be the even wider one of correlating all influences for good mental health.

CORPORA TRIVIALIA.

THE appalling increase in motoring casualties has consequences for the hospitals and the medical profession which call for immediate remedy. Etymologically, it appears, those things are trivial which are met with at the cross-roads,—things common-place, ordinary and familiar. Trivial enough, in this sense only, are the traffic accidents which happen either where three ways meet or elsewhere upon our roads to-day. A Home Office return shows 156,024 persons killed or injured by road accidents in England and Wales during 1928; this total, representing an average of over 460 cases a day, is 12 per cent. higher than that of the previous year. This is not a trivial matter for the hospitals, some of which report that the expense to which they are thereby put runs into thousands of pounds a year, with nothing but negligible contributions from the injured persons to set against it.

Nor is it a trivial matter for the medical practitioner who gives skilled attention in some sudden emergency and too frequently receives neither payment nor even thanks. Recent discussions in the *Manchester Guardian*[1] have revealed that in one instance a practitioner attended as many as 13 cases without receiving any kind of fee. The circumstances, of course, are unfavourable to the normal arrangements for charge and payment. There is a general atmosphere of sympathy; the condition of the patient may prevent his making an offer of immediate remuneration, or a contract to pay; he is often a stranger to the neighbourhood, and the casual helpers who accompany him can hardly be expected to emulate the Good Samaritan by making an immediate financial deposit and promising further payment at their next visit. Liability for the accident may be hotly disputed; insurance companies may be vaguely relied upon; perhaps most frequently of all, there is a general impression that treatment for accident injuries is a gratuitous public service—something which it is the duty of the police or other authorities to provide. So the very mention of charges for professional service is invidious as well as ultimately unavailing. Persons who can afford their own motor-car manage to evade payment, and the motor-cyclist (as common experience shows) is often neither insured against accidents nor worth the cost of suing for the recovery of a fee. Meanwhile the practitioner may have given an hour of his time to dressing an awkward cut or setting a fracture; there may be anxious relatives to interview and ambulances to be arranged for; bandages and even drugs may have been furnished, and domestic servants will have extra work in cleaning up the mess. The practitioner gives no less care to the *corpus triviale* than to his other patients. If his surgery adjoins a high road, the routine of his Sundays —if not of his weekdays as well—is upset by this new significance of the "trivial round and common task." Why, as a county court judge asked recently, should the doctor be expected to give his services for nothing? The medical profession is not the only one to make sacrifices in service of the poor; the legal profession does the same. But it would possibly occasion some surprise in legal circles if the sabbath quiet of a solicitor's home were invaded by a procession of injured persons requiring their dying declarations to be taken, or their last wills and testaments to be drawn up, without prospect of fee or even of any expression of gratitude.

The absence of an obvious remedy is no reason for quiescence in the present state of affairs. In one small way the police can help by furnishing the doctor with the name and address of the patient he has treated. Larger proposals have two objects to achieve. In the first place some comprehensive system of first-aid ought to be evolved by the official and unofficial bodies concerned, the local authorities, the police and those associations which coöperate in the managing of traffic while promoting the interests of the motorist. The Order of St. John of Jerusalem has already done splendid work in organising its home ambulance service for the transport of accident cases; it is also engaged in preparing specifications for first-aid huts suitable for erection by the roadside, to be equipped to minimise the consequences of injuries. If the traffic casualties continue to increase, we may require the Royal Army Medical Corps to work out schemes of dressing stations and field hospitals. In the second place there is the financial difficulty to be tackled. Decent folk will be ashamed to trade upon the gratuitous services of the hospitals and the medical profession. Police authorities can incur expense in connexion with ambulance work; it may be necessary to extend their powers. In any case the treatment of traffic casualties is as much a part of the traffic problem as the maintenance of road surfaces, the planting of trees, or the removal of blind corners. The Road Fund is rightly employed to minimise the risk of accidents; why is it not also available to minimise the consequences of accidents? A fraction of its millions would go far to pay for the care of the victims. Proposals have been made in Parliament that no one should be licensed to take a motor-car or motor-cycle upon the roads unless he first produces evidence that he is adequately insured against third party risks. If present conditions continue, such legislation is inevitable. The companies through which certain newspapers insure their subscribers must have obtained useful data and experience. Can they produce a comprehensive scheme, or must it be left to the State to evolve from its imperfectly coördinated arrangements for workmen's compensation, health and unemployment insurance, and old age and contributory pensions, a universal all-in system, which will cover accidents also?

◆

THE CHILDLESS MARRIAGE.

To gain more control over the processes of reproduction so that he may prevent the birth of the unwanted and secure that of the desired child has long been the aim of civilised man. Towards the realisation of both of these objects he has made great strides, but he has still far to go. Sterility, whether it be that of the male or of the female, is a condition that more often than not defies treatment, and as a result we find that some 10 per cent. of marriages remain involuntarily childless As Miss **F. M. HUXLEY** makes clear in her article on the treatment of sterility in women (see p. 138) the treatment of childlessness, if it is to have any chance of success, must rest on an exact diagnosis, and it is in this direction rather than in the discovery of any new therapeutic weapons that progress is at present being made. In the female the use of insufflation of the tubes or of lipiodol injections allows of a precision in diagnosis that was formerly unattainable. In the male a similar exactness has for many years been possible by ordinary urological methods of examination. But even here progress has been made by the method of spermatozoon counts introduced by Dr. D. **MACOMBER** and Dr. M. B. **SANDERS**. These observers have found that healthy semen contains about one hundred million spermatozoa per cubic millimetre. This figure is remarkably constant for all normal men below the age of 40. Above that age the spermatozoon count tends to fall. In abnormal cases the figure may be reduced to anything from sixty million down to complete azoöspermia. An examination of a large series of cases revealed the fact that in only four instances had a pregnancy resulted when the count had been below sixty million. A spermatozoon count furnishes therefore useful information in diagnosis and prognosis as well as a guide to the effect of treatment.

---

[1] See THE LANCET, pp. 50 and 85.

Another advance that has been made in recent years is the recognition of the part played by diminished fertility in childlessness. If one of the partners in a marriage be highly fertile a relative sterility of the other may be fully compensated. If, however, both be below par childlessness may result even although examination proves neither to be sterile. It is, indeed, probable that in a very large number of childless marriages multiple factors are at work, factors that affect not one but both of the persons concerned. The problem is more complex than was formerly supposed, and in order to discover an answer numerous causes of sterility must be considered, both local and constitutional. The local conditions that effect fertility, such as inflammation of the genital tract, have long been known; the constitutional factors are only now being recognised. They are summarised in the paper read last year before the British Medical Association by Mr. **Kenneth Walker** and in the excellent article by Dr. S. R. **Meaker** published in the *Journal of the American Medical Association* (May 4th, 1929.) For the sake of convenience these constitutional factors in sterility may be divided into four groups—namely, those due to endocrine disorders, chronic intoxications, metabolic faults of extrinsic origin, and conditions of general debility. Of endocrine disorders that affect fecundity the commonest are those of the pituitary and thyroid. As an instance of the sensitiveness of the gonads to chronic intoxications and especially to intoxications of microbial origin, may be cited **Kyrle's** statement to the effect that it is hardly possible to find a normal testicle in adults who have died of infective diseases. The rôle played by faults in metabolism and by diet has been emphasised by the work of many different observers, amongst the first of whom were C. B. **Paul**, T. B. **Osborne**, and L. B. **Mendel**. These workers found that rats brought up on a restricted diet that was sufficient to permit of their normal development remained sterile. To the unknown vitamins in which their diet was deficient they applied the letter E. Observations on the effect of food on fertility have also been made by veterinary surgeons, who have long recognised that dogs fed on cooked meat and biscuits become sterile. Amongst the states of debility that carry with them a low fecundity may be mentioned anæmia and severe neurasthenia.

Some day our methods of examination may become still more exact, so that we shall be in a position to express the fertility of a marriage in figures. This fertility index will be arrived at by multiplying together those of the husband and of the wife. The estimation of the fecundity index of the male is almost within our reach, but that of the female presents difficulties that are at present insuperable. It is interesting to speculate on the way that the problem of the childless marriage will be treated in the future. Some indication is given by the clinics already established on the other side of the Atlantic. At present these clinics are concerned mainly with diagnosis and prognosis, both partners in the childless marriage being subjected to a searching examination not only of the genital tract, but also of their general health, metabolism, endocrine balance, and mode of life. The factors responsible for the diminished fertility are diligently sought out, and as far as possible remedied. But as is so often the case diagnosis in sterility is ahead of treatment and too frequently conditions are found for which no remedies are at present available. In the future it may be otherwise. The time may come when those who intend to procreate children will voluntarily embark upon a régime calculated to raise to its zenith their general physical and reproductive efficiency. The dictum of **August Weismann**, that the germ cells remain unaffected by changes elsewhere in the body, may cease to be given the literal translation accorded to it to-day. It is not easy to believe that whilst the number of spermatozoa secreted is influenced by states of health their quality is unaffected. Although we have no proof that such is the case, on theoretical grounds it would seem probable that the death of a fertilised ovum is sometimes due to a fault in the male cell rather than in the female. If this be so, and if the cause of such a miscarriage is to be remedied, we shall be forced to increase the range of our treatment and to include within its scope the care of the spermatozoon as well as that of the ovum.

◆

THE PLACE OF SURGERY IN EXOPHTHALMIC GOITRE.

Both physicians and surgeons achieve results in the treatment of Graves's disease, but as the condition is further studied and the mass of reliable clinical records increases it becomes more and more clear that the patient's prospects are improved by a close alliance between them. Cure would probably be commoner if treatment were based on an exact knowledge of the cause, but this is at present unknown. If, as was once supposed, Graves's disease were due to a simple over-activity of the thyroid gland the problem would be simpler, but it is now recognised that in this form of goitre the thyroid secretion is in some way altered and made toxic, as well as being increased in amount. The primary mechanism of this alteration and increase of secretion is not understood, although R. J. **Ludford** and W. **Cramer**[1] have shown that there is a difference in the mechanism of secretion in the normal gland and in that of exophthalmic goitre. C. W. **Crile**[2] has lately brought forward evidence in support of the theory that suprarenal over-activity is also an important factor, and that the acute crisis of hyperthyroidism are related to over-activity of these glands. Meanwhile, lacking more information, we can recognise numerous predisposing causes of the disease. Thus, acute infections, focal sepsis, shock or prolonged worry and heredity are factors of importance in many case-histories, and the disease occurs ten times more frequently in the female sex.

The fact that the normal course of exophthalmic goitre is extremely variable leads to difficulty in estimating the value of different forms of treatment. Probably half the patients eventually get well with or without treatment after varying periods of chronic ill-health, while the remainder go intermittently down hill until after long periods of invalidism they are carried off by intercurrent disease or cardiac failure, or die suddenly in the throes of thyroid crisis. But in spite of this difficulty almost everyone would agree that treatment should begin with the eradication of septic foci, and with the patient's removal to surroundings where mental and physical strain are reduced to a minimum, and rest can be obtained. Once these conditions are secured symptomatic treatment would naturally be given; a sufficiency of sleep would be maintained by sedative drugs such as quinine hydrobromide, and the patient would receive a diet unlikely to stimulate the already raised metabolism, but sufficient to meet the increased energy requirement. So much is pretty generally accepted. Often, however, measures of this kind are inadequate, and it is then that the problem of surgical treatment arises. During the last ten years thyroid surgery has made rapid strides on both sides of the Atlantic. Its progress was assisted by the observation of D. MARINE and LENHART that small doses of iodine or potassium iodide, previously taboo in hyperthyroid conditions, produced an artificial remission of the disease. H. S. PLUMMER and W. M. BOOTHBY, working at the Mayo Clinic, then began to use iodine extensively in the form of Lugol's solution as a means of preparing patients for operation, and found that by so doing they were able to prevent the disastrous thyroid crisis, which in the earlier days were the cause of so many deaths at, or shortly after operation. This discovery, coupled with a steady improvement in surgical technique, now makes it possible to review the results of many hundreds of scientifically recorded cases treated by partial thyroidectomy, and to consider the part which surgery should play in treatment. CRILE, for instance, has recently reviewed over 10,000 cases of hyperthyroidism treated surgically; a week or two ago we published[3] a summary of F. H. LAHEY's deductions from the study of the results of 6700 goitre operations, of which 4000 were for Graves's disease or toxic adenoma; whilst in our present issue appears a paper by Mr. W. H. C. ROMANIS, in which he reviews his operative results in a smaller series of 500 consecutive cases. These three observers agree about the great value of surgical treatment. ROMANIS applies the term Graves's disease to cases in which, besides the usual signs of thyroid toxæmia, there is definite enlargement of the heart and definite changes in the eyes. He divides his cases into primary and secondary, the latter being those in which a thyroid toxæmia supervenes on a parenchymatous goitre or toxic adenoma of many years' standing, in which type there is a particular liability to auricular fibrillation. This type is the one referred to by most American authors as toxic adenoma. CRILE, LAHEY, and ROMANIS are at one about the importance of iodine medication before operation without distinction between the two types, although LAHEY says that the beneficial effects of iodine are less obvious in toxic adenoma. As regards the amount of tissue to be removed at operation, all three writers admit a difficulty. They agree that it should usually be considerably more than half the gland and that occasionally a further portion may have to be taken away at a second operation. CRILE and LAHEY both record a mortality of less than 1 per cent., and ROMANIS a mortality of 2 per cent. LAHEY gives a separate quotation for a series of 200 cases of toxic adenomata with auricular fibrillation of which only three died. ROMANIS, though he does not quote separate figures, agrees with both other observers in emphasising the great value of partial thyroidectomy in thyrotoxic fibrillation. All speak of rapidly beneficial effects from surgery, both CRILE and ROMANIS emphasising the need for removal of enough thyroid tissue if the best results are to be obtained. When this is done ROMANIS considers that most patients can return to a normal life within six months although, especially in long-standing cases, a pulse-rate of 80–90, and some exophthalmos, often persist.

[1] Proc. Roy. Soc. B., 1928, civ., 28. (See THE LANCET, 1928, ii., 712.)

[2] Bruxelles Méd., July 7th, p. 1002.

So striking a consensus of opinion from American and English sources cannot fail to impress those who are doubtful about the part surgery should play in the treatment of hyperthyroidism. For what are the alternatives? There is the wait-and-see policy, which, from the nature of the disease, will often justify itself; and there is local treatment of the gland with radium or X-rays. Both these methods yield a high proportion of partial and complete cures, but it is doubtful whether in primary Graves's disease the risks of these more conservative measures are not greater than the risks of operation, whilst in the secondary type operation is certainly the treatment of choice, and should be done before auricular fibrillation has had time to develop. In the absence of a true cure the objections to surgery, or to any other treatment which aims at partially destroying the thyroid gland, are mainly theoretical. These objections are that exophthalmic goitre is due to an unknown stimulus affecting the whole gland, so that however much is removed the stimulus to the remaining portion remains, and a low-grade form of the disease is likely to persist or recur; that there is no accurate way of estimating the amount of gland which should be resected in each case; and finally, that removal of the greater part of a gland so important as the thyroid is unsound as a means of re-establishing its normal physiological action. The problem, of course, is so much an individual one in every case that it is difficult to dogmatise. From a consideration of the results of thyroid surgery for the last few years, it does, however, seem that if medical measures fail, partial and sufficient thyroidectomy by experienced thyroid surgeons offers the sufferer from Graves's disease her best chance of certain and speedy recovery to the extent of being able to live a normal life.

THE KING.

THE clear and detailed bulletins which have been issued during the week have alike informed and reassured the public in regard to the health of the King. It being known that there was a residual abscess communicating with the surface by an oblique sinus increasingly difficult to keep patent, steps were taken to accurately localise the abscess by a radiological examination after the injection of lipiodol. Stereoscopic pictures were taken at Buckingham Palace and these were closely examined and their implications discussed by Sir Stanley Hewett, Sir Hugh Rigby, Mr. Wilfred Trotter, Mr. Martyn, and Lord Dawson on Tuesday, July 9th. After a further consultation the next day the nature of the operation was agreed upon. This operation was performed by Sir Hugh Rigby and Mr. Wilfred Trotter, after which the following bulletin was issued on July 15th.

> The operation on His Majesty the King has been performed. Portions of two ribs were removed, in order that the circumscribed abscess, 1½ in. across, should be directly drained and treated.
>
> The condition of His Majesty is satisfactory.
>
> STANLEY HEWETT. FRANCIS E. SHIPWAY.
> HUGH M. RIGBY. DAWSON OF PENN.
> WILFRED TROTTER.

As His Majesty has now acquired a high degree of general immunity, there is every prospect that the abscess cavity will steadily progress towards healing.

Annotations.

"Ne quid nimis."

SEAMEN'S HOSPITAL SOCIETY.

THE week has seen another milestone passed in the *adventurous career of the Seamen's Hospital* Society, for on Monday last the Duke and Duchess of York declared open the new pathological laboratories built to the design of Sir Edwin Cooper, which are to serve the needs not only of the Seamen's Hospital itself but of the whole neighbourhood in which it lies. Another building opened at the same time was the nurses' home, situated within the gardens of the Royal Hospital School, which is to provide a separate room for each of the 130 nurses who staff the "Dreadnought" itself and its local extensions. The capital cost of both buildings has been fully met out of the fund raised by Viscount Devonport, in 1915 and after, as a lasting memorial to the work of the mercantile marine, and there is a small balance for maintenance. Not as large certainly as some of the optimists on the staff would like. Responding at the banquet to the toast of the laboratories proposed by Lord Devonport himself, the dean, Mr. Percival Cole, spoke of their double function in supplying the known needs of the moment and in organising research to meet the unknown needs of the future; and Prof. R. T. Hewlett, who was in the chair, pictured the endowment of research scholarships as the next objective in view. The scheme has in fact come to fruition at an opportune time. *Even in their previous* domicile the laboratories, under the joint direction of Prof. Hewlett and Dr. Arthur Davies, had served the health departments of five London boroughs and the neighbouring poor-law hospitals. The new unit is fit to play an integral part in any new organisation of *a local health service if only for the* remarkable faith shown by the promoters of a great fund in allotting it to the development of pathology rather than to the provision of beds or clinics. Sir John Rose Bradford, in giving eloquent expression at the banquet to this feeling, was but echoing what was no doubt in the minds of many of his listeners, and his remarks were endorsed by the Member of Parliament for Greenwich who, while disclaiming knowledge of pathology or of the sea, said he knew something of human values at the Seamen's Hospital. It must not be assumed by those who do not know all the facts that the "Dreadnought" is now nothing more nor less than a school of pathology. Since 1901 when, according to Prof. Hewlett, the palæolithic period in the Society's history came to an end, the hospitals for sick and injured merchant seamen under the auspices of the Society have increased remarkably in size and number; there are now 627 beds in the seven establishments, including the *sanatorium* at Bramshott and the hospital at Marseilles. The point is rather that pathological research has always been a tradition in the Society—*was it not at Greenwich* that one of the first cases of acromegaly was described?—and that this tradition is now assured full scope in its further development.

RETROPHARYNGEAL ABSCESS IN INFANTS AND CHILDREN.

ALTHOUGH retropharyngeal abscess is not common, its recognition is important owing to the risks attending spontaneous rupture. According to Greenwald and Messeloff[1] the majority of cases occur during the first year of life, and it is just at this time that an adequate examination of the throat is difficult. Inspiratory and expiratory stridor, aggravated by the horizontal position, is, of course, the outstanding symptom, but diagnosis should usually be possible before it becomes the presenting symptom. A previous history of acute nasopharyngitis is the rule, and in any case in which this is followed by restlessness and unilateral enlargement of the cervical glands, the question of a retropharyngeal abscess should arise. Owing to difficulty in swallowing, mucus collects in the throat and causes the rattling and stertorous breathing so often heard in the later stages. A *snoring, gurgling respiration during sleep is, in fact*, one of the most constant symptoms. Further, the younger the patient and the more rapid the course of events, the more pronounced are these findings. Torticollis is nearly always found, and its presence should suggest retropharyngeal abscess before anything else. As Greenwald and Messeloff point out, the examiner must have a clear conception of a normal throat in infants and children in order to determine, from his brief glance, whether or not there are pathological changes. Even then inspection of the throat in infants is rarely conclusive, and should be followed in all suspicious cases by palpation with the finger. In older children, difficulty is encountered in the examination because of trismus. The pushing forward of one faucial pillar is an outstanding sign found on inspection and one that may easily be overlooked. Slight œdema of the soft palate may also be seen in some cases. The mucosa covering the swelling is at first red, and later, when there is suppuration, the redness fades and the pharyngeal wall becomes pale and somewhat yellowish, feeling elastic and boggy to the finger. Once an abscess has formed, surgical measures and evacuation of the pus are obviously indicated, but in the stage of lymphadenitis, before *true suppuration, great harm may be done by incision*, because generalised sepsis may follow. In Greenwald and Messeloff's opinion, the best results are obtained under light ether anæsthesia, unless the child is desperately ill; the outlook as a rule is excellent.

THE TRAFFIC IN DANGEROUS DRUGS.

THE third annual report made by the British Government to the League of Nations respecting the traffic in opium and other dangerous drugs is now available. It would appear that while the administration of the Dangerous Drugs Acts, 1920 to 1925, seems to have given effect to the principles implied in The Hague and Geneva Conventions, and to have greatly restricted illicit procedures in Great Britain, there is abundant evidence of vigorous illicit commerce elsewhere. *Reports of seizures* have during 1928 been received from the colonies and the Dominions, in particular India and Canada, from the United States, as well as (through the Secretariat of the League) from other countries, notably Egypt and China.

The total amount of morphine and its salts manufactured in Great Britain, by the two Edinburgh firms licensed for the purpose, was 60,021 ounces, a *further* reduction on the previous year. Likewise the amount exported from Great Britain, 40,824 ounces, was greatly less than obtained only a few years ago. Of this exported morphine, 7058 ounces went to Asiatic Countries and 2740 ounces found their way to China, an increase of 1831 ounces over the previous year. The exports of British morphine to Africa, America and Australasia also show an increase over the figures for 1927, while the consignments to European countries showed a considerable decrease. *Of heroin* (diacetyl morphine) 10,704 ounces were manufactured in Great Britain, of which 6038 ounces were exported. It is interesting to note that Indian opium is now almost entirely employed in this country for pharmaceutical purposes to the exclusion of Persian and Turkish opium, which latter were formerly regarded as the more appropriate sources of the alkaloids. It is also to be noted that in addition to the import of raw opium 6017 ounces of crude morphine were imported from India (presumably from the Government factory) and used for the production of the alkaloid or its salts. No less than 64,091 ounces of morphine were last year used for the making of codeine, an alkaloid not at present included within the provisions of the Hague or the Geneva Conventions. A novel departure has been made whereby 4934 ounces of cocaine were manufactured last year for the first time in this country by the one firm (May and Baker, Battersea) licensed for this purpose. The imports of cocaine (9353 ounces) were less by 6000 ounces than in 1927. On the other hand the exports of cocaine salts (3950 ounces) showed an increase on the previous year, such increased exports being chiefly to China and New Zealand. The exports of heroin (diacetylmorphine), generally speaking, show a similar tendency, while in the case of "artificially dried opium" there was a curiously large increase in the consignments to South Africa—viz., a total of 195,000 lb. or an excess over the figures for 1927 of 88,428 lb.

---

[1] Greenwald, H. M., and Messeloff, C. R.: Amer. Jour. Med. Sci., June, 1929, p. 767.

From press reports it would appear that in more than one case the diplomatic privilege which secures immunity from search to consignments of goods to embassies and legations has been abused by the inclusion of dangerous drugs. Meanwhile the Permanent Central Opium Board has held its second session at Geneva. The relation of that body to the Advisory Committee on Traffic in Opium remains somewhat indefinite, though close coöperation is naturally deemed to be essential. The Board nominated certain officers for the secretariat and these await the approval of the Council and the Secretary General of the League. After prescribing the forms of statistical returns of import and export of the scheduled drugs the Board adjourned till October.

VARIOLA IN RABBITS.

THE variolous origin of vaccinia is now generally accepted as a fact and anyone familiar with the correct technique has no difficulty in producing a strain of vaccinia by passing the virus of small-pox through an appropriate series of animals. An important difference between small-pox and the disease produced by the virus thus modified consists of the inability of the latter to spread from one individual to another by any means other than actual inoculation of virulent material. So far as we are aware the disease in animals other than man has always shown this absence of infectivity, and if this characteristic can be taken as the distinction between variola and vaccinia an outbreak among laboratory rabbits described by S. Nicolau and L. Kopciowska[1] fully merits the name of variola.

The epizoötic occurred in April of this year among some 50 rabbits in a room where there had been no animal infected with vaccinia since the previous September. Two animals undergoing antirabic immunisation developed simultaneously a peculiar form of acute coryza, with purulent nasal discharge, later becoming sanguineous with the formation of blackish crusts round the nares. Respiration was difficult owing to the nasal obstruction and the animals died on the fifth and eleventh days respectively. Each rabbit showed three or four small papules on a previously shaved area on the flank. Within 40 days symptoms of the illness had appeared in 34 other rabbits housed in cages in the same room, which measured approximately 26 feet by 60 feet. The symptoms varied and out of 23 which died six had acute coryza, two acute coryza and cutaneous papules, eight coryza and conjunctivitis or kerato-conjunctivitis, one of these having orchitis in addition, one kerato-conjunctivitis alone, three orchitis, and three showed no definite symptoms. Of these last three one on dissection was found to have a pustule on the nasal mucous membrane, and several of those with coryza had one or more pustules on the tongue. Orchitis did not occur among the rabbits which recovered, but otherwise their symptoms were similar. Post mortem all the dead animals were found to have a greatly enlarged spleen. Purulent pneumonia was found among those which had shown coryza before death, and the meninges were frequently adherent, a condition typical of cerebral vaccinia. These adhesions were more marked in the rabbits which had shown no definite symptoms while alive, suggesting a special localisation of the virus in the brain in these cases. The skin papules were typical of the lesions of vaccinia. Out of 12 attempts the virus was successfully recovered every time from the tissues of rabbits which died in the epizoötic, nine times from the brain, twice from cutaneous papules or pustules, and once from the testis. This virus proved highly virulent for rabbits, killing with the typical signs of vaccinia in four to six days when introduced into the testis or brain, and on skin inoculation producing a characteristic eruption intermediate between that of neurovaccine and dermovaccine. Cross-immunity experiments demonstrated the variolous or vaccinal nature of the virus. Animals immunised with ordinary vaccine were completely resistant to the virus from the epizoötic both with cutaneous and subdural application. Likewise the animals which recovered were refractory to ordinary vaccine. Moreover, a number of rabbits which had been through the epizoötic without showing symptoms also proved to be immune to ordinary vaccine.

The authors of the paper have nothing definite to suggest as to how the infection arose or was disseminated beyond vague speculations as to the possibility of its having been latent in the dust of the room for seven months and been carried by air and dust. *It is noticeable that no mention is made of* the possibility of its importation and spread by the attendants of the animals. It is suggested that seasonal influences played a part, mainly on the grounds apparently that the outbreak coincided with the "recrudescence of the epidemic of human small-pox observed particularly in England"—a recrudescence which actually consisted of a comparatively small number of imported cases of a virulent type which achieved a disproportionate international prominence.

The interest in the outbreak reported by Nicolau and his colleague seems to lie in the virulence and infectivity of an outbreak among rabbits. Vaccinia among rabbits and other animals is generally regarded as a mild and comparatively innocuous disease which can be relied on to breed true to type—a fact of which advantage is sometimes taken in the preparation of vaccine used for protective purposes.

THE TAVISTOCK CLINIC.

THE problem of functional nervous disorder is becoming increasingly important. It is dealt with to a certain extent in consulting practice, but many thousands of patients with limited means have no one to cater for them. The Tavistock-square Clinic is making heroic efforts to fill a gap many times larger than its utmost capacity. Its work has increased by 30 per cent. in two and a half years, and the activities of the Children's Department by no less than 57 per cent. in one year. Its services are in ever-increasing demand among hospitals, police-courts, and private patients who cannot afford a consultant. The Clinic has now, however, reached saturation point. Its work is carried on by 25 regular physicians, and in only seven consulting rooms, and every part of the building is utilised to the utmost. The result is that the waiting list has twice had to be closed in the last 18 months. These limitations have produced what Dr. H. Crichton Miller calls "very active compensatory phantasies of extension." The phantasies, however, are of a constructive kind, and are embodied in a well-developed scheme. Mental hygiene, as he points out, can no longer be considered as the fad of a handful of men and women. In all countries where it has been systematically practised it has proved as necessary and valuable to the health of the community as the work of stamping out tuberculosis, cancer, or infantile mortality. The extension scheme has been worked out in such a way that it can be realised step by step as the necessary funds are subscribed. The first need is for an institution where treatment, teaching, and research can be conducted on a scale more approaching the needs of the country. The building will cost £80,000, and its endowment another £100,000. Observation homes for mal-adjusted children will cost £20,000. The most urgent necessity, however, and one which is hampering the work of the Clinic at the moment, is for a hostel for patients who cannot afford nursing homes, and are not well enough to stay in cheap lodgings and hotels. The hostel proposed will house 20 patients, and will cost £13,000; when once established, it will be almost self-supporting. It may be noted that the appointment of a Deputy Director of the Clinic, Dr. J. D. Rees, at the beginning of the year, which was made possible by an anonymous donation, has resulted in an immediate improvement in the coördination of the staff. New activities have been initiated in every branch of the work, and especially a system of record-keeping which will facilitate treatment, administration, and research. The Clinic is, therefore, prepared for further expansion, and it remains for those who appreciate its importance to give it the financial assistance which it is well-adapted to transmute into mental efficiency and happiness.

---

DENGUE IN ATHENS.

THE clinical aspects of the Athens epidemic of dengue[1] were minutely studied, but no account of them has hitherto been available. We therefore welcome a recent report[2] by physicians who had immediate access to over 1000 cases. In October, 1927, the disease suddenly made its appearance in the city, but the outbreak was a small one and was extinguished in November. In mid-June of 1928 a few sporadic cases were noted, and the infection spread so quickly that towards the end of September quite nine-tenths of the population were attacked. In the Piraeus, which has direct communication with Athens, dengue was disseminated more rapidly than elsewhere. The election of August 19th and the constant interchange of population between capital and provinces which this entailed during the summer season all contributed towards its propagation.

Amongst the prodromata of dengue slight headache and otherwise inexplicable fatigue are noted. In the invasion period the muscles of the eye are implicated, the patient suffering especially on lateral movement. The joints are generally painful. The fever rises gradually, sometimes with a rigor; a temperature of 104° or 105° F. may be recorded. In the invasion period the pulse-temperature ratio is normal. Pains in the body become intense, so that every movement is accompanied by great difficulty. In the Athens epidemic the gastric phenomena were remarkable. Nausea usually accompanied the primary rise of fever, but the straining at vomit was so intense as often to rupture small arterioles in the palate, pharynx, or tonsils, with effusion of blood into the vomit. The primary eruption was characterised by hyperæmia of the face and neck, and suffusion of the conjunctiva. This reddening was sometimes so slight that it escaped detection and in 10 per cent. of the cases no primary eruption was noted. The febrile illness was occasionally over within four or five days, and though in certain cases fever lasted as long as 23 days, in 85 per cent. it ended within six days by a typical crisis lasting 3–6 hours. Intense headache usually persisted for some 80 hours after the fall of temperature. As a rule there was a fall of temperature on the third day, accompanied by a sense of well-being, and this lull might last for 30 hours; afterwards, however, the temperature soon began to rise until it had reached its former maximum. The second crisis may take place on the fourth, fifth, seventh, or even the ninth day; or the fever may end by lysis. After the first drop of temperature bradycardia becomes noticeable, and these observers say they have often recorded a pulse of 70 with a temperature of 104° F. Not only is there a great slowing of the pulse, but also a fall in pulse tension. A secondary eruption was a pretty constant feature, usually appearing on the second or third day after the decline of fever. It might be roseolar, morbilliform, scarlatiniform, or even petechial. The exanthem itself lasted 12–30 hours and in disappearing was accompanied by furfuraceous desquamation. Examination of the blood revealed a constant leucopenia; a count of 3000 leucocytes was common and occasionally it was only 1500. The mononuclear element was increased to 30–50 per cent. of the total. Convalescence was marked by debility, emaciation, loss of appetite and taste, and relapses were rare (5 per cent.). In a relapse the exanthematous eruption, pain and bradycardia are all repeated. Usually an attack of dengue provides an absolute immunity, but very rarely it may be repeated two or even three times, as was especially noted in the case of refugees from Asia Minor.

Unfortunately the Athens epidemic has added little to our knowledge of treatment. The authors of this report are convinced that neither the salicylates nor urotropine, whether given by the mouth or intravenously, have any decided specific effect. In their protocols they record seven deaths, of which the direct cause is attributed to dengue, but post-mortem examination was not obtained.

THE NEW PHARMACOLOGICAL LABORATORIES IN MANCHESTER.

ON Wednesday of last week, Mr. F. H. Carr, late President of the Society of Chemical Industry, opened the new laboratories which Messrs. Benger's Food, Ltd., have presented to the Medical School of Manchester University. The new laboratories are for the study of pharmacology, pharmaceutical chemistry, and biochemistry in its relation to pharmacology. They consist of a room suitably equipped for experimentation on animals and man, with a preparation room attached, a biochemical laboratory, a pharmaceutical laboratory with separate balance and furnace rooms, a demonstration theatre to accommodate some 50 students, private laboratories for the head of the department and a lecturer, and a room to be used as a library and secretary's room. There are three small rooms near by in which animals can be housed under ideal conditions. This extension has been rendered possible, firstly through the removal of the department of pathology to York-place, where it is in more immediate contact with clinical work and the related departments of bacteriology and public health, and secondly through the generous donation of £2000 in memory of Frederick Baden Benger. This was the Benger who coöperated with Sir William Roberts in the eighties of last century in the production of an efficient pancreatic extract. Roberts described it in his Lumleian lectures as "an almost faultless pharmaceutical preparation with high diastatic and proteolytic properties of the gland in a highly concentrated degree." Other digestive products were subsequently put on the market to meet Roberts's wishes. The study of pharmaceutical chemistry in Manchester goes back a good many years, the first systematic course having been given in 1824 by John Dalton, F.R.S., then president of the Literary and Philosophical Society. The lectures, about 15 in the course, were given in the evenings at seven o'clock, and Dalton, after explaining the first principles of chemistry, proceeded to apply them to investigations respecting the materia medica, and to other medical purposes. The items on his printed syllabus were these: Heat or Caloric, Constitution of Bodies, Chemical Syntheses and Analyses, Simple or Elementary Gases, Elementary Solids, Compound Bodies, Alkalies, Acids, &c., Earths, Sulphurets, Metals, Vegetable Kingdom, and Animal Kingdom. Dalton received fees totalling £27 8s. 9*d*., from which he had to deduct his expenses which amounted to £10 10s. It seems that he maintained his connexion with the medical school for at least six sessions, and that towards the end he had three separate classes, each attended by eight or nine students. The pharmacological department at Manchester owes its present efficient condition to the influence, material support, and devotion of the late Prof. D. J. Leech, who organised and fully equipped it for its needs in 1884, and in whose memory a departmental library was built up. He endowed the Leech chair of materia medica and therapeutics which he held himself for some years, and in which he was succeeded by Prof. R. B. Wild, who retired in 1927. Since then the chair has not been filled but a readership is held by Dr. A. D. Macdonald. It is hoped that the present scheme will provide a modest beginning out of which may grow a school of pharmacology and pharmaceutical chemistry, comparable in its influence to the other schools of the University.

DAMPNESS IN HOUSES.

THAT damp is a potent source of illness is a traditional belief in support of which more and more evidence is slowly accumulating. The proof is all the more difficult in view of the fact that the influence of damp, or more correctly of cold damp air, can be neutralised by adequate clothing, by exercise and to a limited extent by diet. Careful investigation into the housing conditions of children suffering from acute rheumatism led Dr. R. A. Miller to the conclusions that nearly two-thirds of those children lived in damp rooms. Largely at his instance the Science Committee of the British Medical Association asked the Royal Institute of British Architects for assistance in investigating the reasons for dampness in houses, with a view to a plan of action for its prevention. The Institute, having addressed a questionaire to medical officers of health throughout the country, have now considered the replies and published the result.[1] In new houses, that is, houses less than ten years old, porosity or faulty construction of the walls has been found to be the principal cause of dampness; rain beating against a wall with a strong wind blowing or capillary action causes the penetration of moisture to the interior. Attempts to make walls impermeable by cement coverings often fail owing to the development of shrinkage cracks; the true remedy is a cavity wall. There has been a post-war tendency to cut down the overhang of the eaves, a potent device for keeping external walls dry. A curious fact elicited by the inquiry is the absence of damp-courses in new dwellings and defects in those provided, conditions which call for the stricter supervision of the process of building and the prohibition of the use of ineffectual damp-course materials; these might well be subject to standard specification. Dampness arises in a number of cases from failure to cover the whole of the surface of the ground within the building with concrete; if damp is present, as from rise in the level of the subsoil water, a layer of hard broken material must be interposed between the concrete and the soil in order to obtain a completely dry floor. In older buildings the chief causes of dampness are the absence of a damp-course and inadequate maintenance, especially of roofs and rain-water gutters. Sufficient care is not taken to secure a thoroughly waterproof roof; often the pitch is unsuitable; pantiles or interlocking tiles of unsatisfactory manufacture have been used or flat tiles and slates with perishable nails or inadequate overlap. Roofing tiles could, with advantage, be standardised. Another source of damp is defective cement fillets used to fill up intervals between roofs and walls; cracks often develop in these fillets owing to the shrinkage of the mortar or the roof timbers. Walls cannot be protected by bedding tiles in mortar; capillarity comes into action. Condensation on internal walls is of some import in older houses; the construction of the house must allow of the wall being rapidly heated up. Certain amendments to public health legislation are necessary, it seems, to provide a complete safeguard so far as resistance to the penetration of damp into buildings is concerned; the building by-laws as they now stand do not suffice. It is noteworthy that this valuable report, issued after much labour and research and of far more importance than its length would indicate, has been rendered possible by the coöperation of clinical physicians, medical officers of health, and of architects.

THEFTS FROM DOCTORS' CARS.

AN industrious member of Parliament has been drawing the Home Secretary's attention to the thefts of drugs from medical practitioners' motor-cars. Supplementary questions invited Mr. Clynes to suggest to "the medical fraternity" that, if these losses continue, "some method will have to be adopted of enforcing penalties"; was he not aware that criminal negligence on the part of miners and railwaymen was invariably punished with imprisonment? The Home Secretary replied with perfect propriety that such thefts had occurred, that the [illegible] regarded them as unconnected with the drug traffic, and that it was desirable that the medical profession should do its utmost to minimise the danger. Yielding to the torrent of "supplementaries," he added that, if this publicity were not sufficient warning, "further steps might be taken." To the member of Parliament who put the questions the remedy is simple—a one-clause Bill for the more frequent imprisonment of doctors for criminal negligence. Be it therefore enacted that on and after the first of April any person whose goods are stolen shall, if he be a registered medical practitioner, be guilty of felony, and sentenced to penal servitude. The law already forbids cars to be locked when left at parking-places. An amendment to compel the equipment of medical motor-cars with barbed wire and machine-guns would rightly be ruled out as too militaristic for this peaceful age. Marked economies in police administration will follow by adopting the convenient principle of arresting the owner, rather than the thief or receiver, of goods that have been stolen. One point remains, which can easily be settled on the committee stage of the Bill. Will it be an aggravation of the crime—or will it, on the other hand, be a good defence—if, as sometimes happens, not only the contents of the doctor's car are stolen, but the whole car, contents and all?

SULPHUR AND SALICYLATES IN ACUTE RHEUMATISM.

EXCEPT at spas, the therapeutic use of sulphur has not received very much attention in this country, but in France and elsewhere on the continent this element is employed in colloidal form with increasing frequency. Thus two French workers[1] have lately described its successful use in a case of severe cardiac rheumatism which had proved completely resistant to salicylates. The patient was a woman of 24 who had suffered twice previously from acute articular rheumatism without any cardiac involvement. Her third attack began with a sore-throat followed by acutely painful swelling of the joints, and despite the administration of about 90 grains of sodium salicylate daily by the mouth she had developed signs of gross cardiac failure within ten weeks. Intravenous injections of sodium salicylate in glucose had little effect upon this condition, but some amelioration of symptoms was obtained by substituting intravenous injections of colloidal sulphur, the dose being gradually worked up from 0·25 to 2 c.cm. daily. The patient's condition became worse again, so sodium salicylate was recommenced, this time in conjunction with the sulphur. From this moment improvement set in and slowly but surely the patient recovered, so that she was able to return to work nearly eight months after the beginning of her illness. The case is also recorded of a boy of 17, who developed a severe pericarditis in the course of his first attack of acute articular rheumatism. Here again the malady was very resistant to medication by salicylates, but the addition of colloidal sulphur intravenously quickly brought about a cessation of the acute rheumatic manifestations. Leoper and Vahram, who experimented with sulphur in acute articular rheumatism in 1915, are quoted as giving guarded opinions about its employment when cardiac complications are present; they uttered a special warning against injecting sulphur into the veins in the course of a bout of acute endocarditis. Marchal and Thiolat, however, believe that with care there is no danger in its use; it does not even cause the sclerosis of veins which may lead to difficulty when intravenous salicylate is given repeatedly. The exact action of the sulphur is still, of course, in dispute. It has been held that it has a purely local action in the neighbourhood of joints where there is a veritable shortage of sulphur, but its apparent success in cardiac rheumatism, when employed with salicylates, suggests that this hypothesis is not a complete explanation. Marchal and his collaborator hold that it is upon the infective process that sulphur exerts its influence, probably by producing some metabolic change. They say that the action of mercury and of bismuth may be accentuated and that large doses may be given without danger if sulphur is employed at the same time, and they think it possible that sulphur plays the part of a catalyst in promoting the action of salicylates on rheumatism.

MEDICO-LEGAL PROBLEMS.

Lord Riddell, the newly elected President of the Medico-Legal Society, has usefully brought together in one volume[1] his papers read before that body in recent years on such topics as the legal responsibility of the surgeon, the ethical, legal, and medical aspects of abortion, the law and ethics of medical confidences, and the question of sterilising the unfit. The standpoint is that of an observer, himself well acquainted with the medical as well as the legal view, who sees new problems created by developments in surgery and other sciences and by the quickened popular interest in racial and social concerns. Prof. Gilbert Murray lately remarked, in an address to the Hellenic Society, upon the shaking of the intimate beliefs, philosophies, and standards of modern man, the rejection of Christianity by Russia and of Islam by Turkey, the collapse of Victorian ethics and cosmology, and the developments in physical science and psychology. "Impulses hitherto deemed unspeakably obscene or malignant have not only been recognised as part of the human make-up but have received a quite disproportionate welcome from the public." There is all the more need of a calm statement of modern professional practice and its legal aspects in such matters as the "Medico-Legal Problems" with which Lord Riddell deals. If the law requires to be changed to keep pace with present conditions, the public must be educated. Lunacy and mental deficiency, says Lord Riddell, are unpleasant subjects which most people are loth to face or discuss; his chapter on sterilisation focuses attention on the results of shirking a well-considered policy; the central and local authorities concentrate, he says, upon individual treatment without due regard to the interests of the community. Abortion, hitherto a matter for masculine ecclesiastics, lawyers, and doctors, he regards as mainly a question for women, though he deprecates the view of some German writers that every woman, by virtue of her right over her own body, is entitled to decide whether the fœtus shall become an independent human being. Of sterilisation as a means of birth control he expresses no ethical estimate, but desires to see the subject "ventilated and not left exclusively in the hands of the high priests of obstetrics and gynæcology and their prompting and consenting patients." Mr. Justice McCardie has lately been saying at Birmingham Assizes that the public must face the question of sterilisation: it is terrible, he says, that we cannot prevent a woman bringing eight or ten children into the world cursed with the taint of mental deficiency. If people are to face these questions, a well-equipped observer can perform a great public service by setting forth the facts and tendencies clearly and impartially. In this task Lord Riddell has achieved an unquestionable success.

TRAINING IN HOSPITAL DIETETICS.

About five years ago the managers of the Royal Infirmary of Edinburgh equipped and staffed a special department for dietetic work. At first the work was confined to out-patients, but later assistance was sought for patients in hospital, mainly in surgical wards and special departments. More recently two small wards of six beds each have been opened in connexion with the new clinical laboratory, in order that controlled metabolic observations may be possible. The dietetic staff closely coöperate in these investigations. For the past two years special instruction and experience in dietetics has been offered to nurses who have finished their general training. In addition a six months' course for pupil dietitians has now been instituted. Candidates for this require to have had a preliminary training of two or three years in domestic economy and the chemistry of foods in order to benefit from the course. Instruction is given in dietetic work of all kinds, including the calculation and construction of dietaries for all types of metabolic disease and for research purposes. Experience in the preparation of foods is also available. The course is thoroughly practical and those who have taken it have readily found opportunity of making use of their special knowledge.

THE SHORTAGE OF WATER.

A memorandum issued by the Ministry of Health to water authorities calls attention to the shortage arising from the abnormally low rainfall and discusses the provision of supplementary supplies from neighbouring authorities where there is a local shortage. If existing supplies cannot readily be supplemented, all reasonable measures should be taken early, even at some inconvenience to the consumer, to conserve them. The need for drastic economy and for the detection and prevention of remediable waste is urged. Intermittence of domestic supply is not recommended except in cases of actual necessity. There is always some risk of contamination where pipes are not fully watertight or for other reasons the influx of impure water is possible. In any sustained dry period the risk of pollution is enhanced, and must be kept under close observation. Wherever the purity of the water is threatened, special means of purification should be undertaken. The readiest of these is chlorination, which should be employed only under expert supervision. Properly chlorinated, water which ordinarily could not be used without some danger to health may be safely put into service, and some water authorities may have to resort to such supplies in order to meet the present emergency. Where general measures of purification are not practicable, if any serious danger of pollution is ascertained, the individual householders should be impressed with the need for boiling the water used by them.

---

[1] Medico-Legal Problems. London: H. K. Lewis and Co. 1929. Pp. 100. 5s.

Where expense has to be incurred by a local authority in relieving water shortage in their district County Councils and Rural District Councils are empowered, under sections of the Local Government Act, 1929, to contribute to the expenditure.

THE B.M.A. MEETING.

THE ninety-seventh annual meeting of the British Medical Association opens at Manchester to-day (Friday) with the first session of the Representative Body, which again meets under the chairmanship of Dr. C. O. Hawthorne. A strenuous four days' work is anticipated by the representatives, and the agenda contains subjects lending themselves to almost unlimited discussion, including a national maternity service, a specialist refraction service, the relation of the general practitioner to hospitals and the public health service, and such topical matters as the licensing of motor drivers before their accidents and the care of their injuries afterwards. At the annual general meeting, on Tuesday next, the new President, Prof. A. H. Burgess of Manchester, will be invested with the badge of office and the President-elect for 1930, Prof. Harvey Smith of Winnipeg, will be introduced to the meeting. The scientific sessions begin their deliberations, as usual, on the Wednesday morning. A popular lecture on Frogs and Men will be given by Prof. A. V. Hill, F.R.S., on Friday, the 26th, and the following day will be taken up by an excursion to Colwyn Bay. The annual exhibition will be on view from Monday afternoon until Friday.

INDEX TO "THE LANCET," VOL. I., 1929.

THE Index and Title-page to Vol. I., 1929, which was completed with the issue of June 29th, is now in preparation. A copy will be sent gratis to subscribers on receipt of a post-card addressed to the Manager of THE LANCET, 1, Bedford-street, Strand, W.C. 2. Subscribers who have not already indicated their desire to receive Indexes regularly as published should do so now.

DONATIONS AND BEQUESTS.—Dr. H. T. George, of Hampstead and Cardiff, left £1000 to St. Bartholomew's Hospital and £100 to St. Dunstan's Hostel for the Blind.—Mr. Edwin Brough, of Hastings, left £1000 to the East Sussex Hospital.

THE OSLER CLUB.—A meeting of the Osler Club was held in the evening of July 12th to celebrate the eightieth anniversary of Sir William Osler's birthday. Sir Archibald Garrod delivered the Oslerian Oration which marks these annual occasions; his subject was the Power of Personality, as exemplified in the teaching and practice of medicine by Osler. A discussion followed, which was opened by Dr. A. G. Gibson, and joined in by Dr. G. Feine, Prof. F. R. Fraser, and others. A selection of Osler's writings on Medical Education was displayed, and many messages were read which had been received from friends and corresponding members of the Club abroad. Among those present were Sir D'Arcy Power, Sir William Hale-White, Sir F. G. Kenyon, Dr. Andrew Balfour, Mr. Hugh Cairns, Mr. Philip Franklin, Dr. Marshall Fulton, Mr. R. H. Hill, Dr. Gerald Horner, Mr. Muirhead Little, Dr. J. D. Rolleston, and Mr. Paterson Ross.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

CCXCV.—THE TREATMENT OF STERILITY IN WOMEN.

PART I.—GENERAL CONSIDERATIONS.[1]

THE questions of sterility on the one hand and that of over-fecundity on the other seriously affect the lives of women of all classes. The doctor is consulted with almost equal insistency on the problems of how to acquire the wished-for child, at almost any cost, and of how to avoid acquiring another child for a time at least.

Diagnosis of the Cause of Sterility.

In dealing with sterility, every effort must be made to diagnose with exactitude the underlying cause or causes before any treatment is initiated. Cases of "functional" sterility become fewer as methods of diagnosis improve. Treatment of a woman should not be started, even when an obvious lesion exists, without proof that her partner is normal. Until comparatively recently the question of male sterility was not seriously considered. It is still usually the woman who seeks advice, though I notice a growing tendency among my patients to come with a history that their husband has been examined and found normal. It is, generally speaking, easier to deal with the male side of sterility in private practice than among hospital patients. Clinical facilities for the necessary examinations and tests are not great in hospital, and under the conditions that do exist the patient has diffidence in voicing his requirements.

Examination of the husband may be direct or indirect. Direct examination involves, as well as history-taking and examination for any physical disability which might interfere with fruitful intercourse, the microscopic examination of the semen for active spermatozoa. Indirect knowledge of the husband's condition with complete knowledge of the wife's reception can be obtained in positive cases by microscopic examination of specimens from the cervix uteri taken within two to three hours of normal coitus. If active spermatozoa are found, the search for the cause or causes of sterility are much narrowed down. If impotence exists in the presence of living spermatozoa, artificial insemination can be tried (see below), but should not be undertaken until the woman has been examined and treated for any lesion which might prevent a successful issue.

Investigation of the History.

At a woman patient's first visit, attention should be paid to her general appearance, and guidance as to treatment may be gained from a careful history, the main points being—age; general health, past and present; duration of married life; whether the sterility is primary or secondary (if secondary, details of previous confinements should be given); menstrual history, as regards age of onset, periodicity, and flow; presence of any abdominal pain or vaginal discharge, or of dyspareunia. The incidence of coitus, its frequency and the position taken should be ascertained; also details of any contraceptive measures used in the past. The family history may also be of interest. The reason for obtaining information on most of these points is obvious. Regarding the menses, although we know that pregnancy can and does occur without them, a poor menstrual history is often associated with poor development of the pelvic organs and, especially if the patient is comparatively young, good results can be obtained with treatment directed towards stimulating development. With regard to dyspareunia, often associated with incomplete coitus, as a cause of sterility, it is surprising how long patients continue to suffer without seeking advice. Material help can be given in some cases regarding the best time for fruitful intercourse, which, in my experience, is the first week after the period. R. Kurzrok recorded two cases recently where Jewish women, misinterpreting the old Talmudic Law, waited consistently for a full fortnight after each period before intercourse took place. When, according to advice, intercourse took place within a week of the onset of flow, both women conceived readily.

---

[1] Part II., on Local Measures, will appear next week.

It is also important that the wife should be in a positive phase of sexual excitability. Although it is very doubtful whether the cervix actually gapes during orgasm, there can be no doubt that receptivity is increased when the emotion of both parties reaches its height simultaneously.

The use of contraceptives has frequently been cited as a cause of sterility. In view of the very powerful drugs we use in the treatment of cervicitis and infections of the lower part of the genital tract, and falling statistics, my view is that such contraceptives as quinine pessaries can hardly be so seriously culpable. Any device introduced and left in the uterine cavity, such as the gold wish-bone pessary, or caps which fit tightly on to the cervix and hold up the normal secretions are almost certain to produce inflammatory changes and are much to be deprecated.

Position during and after Coitus.

Conception takes place more readily when the cervix is directly inseminated. In its normal position in the posterior fornix this is best obtained by the "normal" position for coitus—the wife lies on her back with the knees flexed and separated. Free access is obtained, energy is in no way restricted, and there is the further advantage that the semen can be retained in the vagina. In patients with lax vagina and mobile uterus there is a tendency for the uterus to fall into the retroflexed position when the thighs and knees are flexed. Such patients after intromission should straighten and adduct the legs. More important than the position during coitus, when the cervix is not well placed, is position after coitus. Semen can be retained in the vagina by contraction of the sphincters and a change into the semi-prone position. Muscular movement can then further aid insemination of the cervix. It is in these cases that a saline or mildly alkaline douche before coitus may further help by retaining the vitality of the spermatozoa, which is soon destroyed in the natural acid medium of the vagina.

Methods of Examination.

This involves a survey of the patient's general development, the condition of her thyroid, her pulse, and so forth, and a detailed local and bimanual examination. Added to these are the methods introduced in the last few years of per uterine insufflation and injection of the Fallopian tubes—methods which have revolutionised our views on cases of sterility. Before these methods of diagnosis were available, the presence of tubal lesions could be determined only by bimanual palpation or suspected from the history associated with minor degrees of pelvic peritonitis. Now conditions of blockage are found when little suspected and their site defined with a view to treatment. In certain cases the method of diagnosis alone has worked a cure.

Uterine Insufflation.—It was in 1920 that Rubin read his first paper on insufflation and not long afterwards S. Forsdike and others were successful in obtaining good results from the injection into the uterus and tubes of a solution opaque to X rays. Now both methods are greatly improved and widely practised. Neither can be used in inflammatory conditions of the tract, when uterine hæmorrhage exists, on account of the risk of air-embolism, or in patients with cardiac or other serious lesions. The insufflation method can be practised without anæsthesia and is indeed only complete under these conditions, because the patient's sensations are of value in diagnosis, localised pain being felt at the site of blockage. The apparatus consists in a cannula that enters the uterus, fitted with an "acorn," which pushes firmly into the external os. Air or gas is driven through the uterus and tubes at a known pressure. Leakage can only be prevented by firm pressure of the acorn into the os, firm traction of the cervix downwards on to the acorn or clamping the cervix on to the cannula. Many patients do not bear this procedure well. If we use anæsthesia for insufflation, it is possible to say only whether the tubes are patent or impermeable. For the anæsthetised patient dilatation is performed and a cannula that fits tightly into the cervix is used.

Injection.—Lipiodol is the fluid of choice for the injection method. Since its presence in the pouch of Douglas has been found by experience to be innocuous, the only disadvantage of this method is the obvious one that X ray apparatus must be available for its practice. In other respects it is essentially more satisfactory than insufflation, the apparatus being simple (a 10 c.cm. serum syringe attached to a cannula with acorn, as described above), leakage obvious, and the results to be seen, rather than to be interpreted. Injection can be done equally successfully with or without anæsthesia according to the requirements of the patient, and a permanent record can be kept of the results obtained.

FRANCES M. HUXLEY, M.D., Ch.B. Manch.,
Surgeon to the South London Hospital for Women.

The Services.

ROYAL NAVAL MEDICAL SERVICE.

Surg. Capt. B. P. Pick to *Egmont*, for Malta Hospital.

Surg. Comdrs. L. W. Gemmell to *Ganges*, for R.N. Sick Quarters, Shotley; G. H. Hayes to *Pembroke*, for R.N. Hospl. Gt. Yarmouth; J. F. Hayes to *President*, for Recruiting Headquarters; R. F. Quinton to *Defiance*; H. H. Ormsby to *Vernon*; and J. H. McDowall to *Pegasus*.

Surg. Lt.-Comdr. A. W. McRorie to *Medway* and (on commg.).

Surg. Lt. J. K. G. Way to *Ark Royal*.

ROYAL NAVAL VOLUNTEER RESERVE.

Surg. Lt. (D.) C. T. Pomeroy to *Vivid*, for R.N. Barracks, Devonport.

ROYAL ARMY MEDICAL CORPS.

Capts. P. A. Stewart (prov.) and W. C. Mackinnon to be Majs.

ARMY MEDICAL RESERVE OF OFFICERS.

2nd Lt. R. H. Bland, from Gen. List, Inf., to be Lt.

TERRITORIAL ARMY.

Col. J. S. Riddell (late R.A.M.C., T.F., retd.) to be Hon. Col. R.A.M.C. units, 51st (Highland) Div., T.A.

Capt. R. J. W. A. Cushing to be Maj.

C. R. Greene to be Lt.

Supernumerary for service with O.T.C.: Lt. H. S. Allen to be Capt.

TERRITORIAL ARMY RESERVE OF OFFICERS.

Maj. H. G. L. Haynes from Active List, to be Lt.-Col.

Maj. C. Webb-Johnson having attained the age limit relinquishes his commn. and retains his rank.

Lt. A. S. Gough, from Active List (Supern. for serv. with Med. Unit, Univ. of Lond. Contgt., Sen. Div., O.T.C.), to be Lt.

ROYAL AIR FORCE.

AUXILIARY AIR FORCE.

Flying Officer J. S. Jerome, N. 605 (Co. of Warwick) (Bomber) Squadron, to be Flight Lt.

INDIAN MEDICAL SERVICE.

Temp. Capt. Mangharam Rochiram Lalvani relinquishes his temp. commn. and retains his rank.

The undermentioned relinquish their prob. appts.: Lts. W. Walsh and G. J. O'Connor.

Special Articles.

FOURTH IMPERIAL SOCIAL HYGIENE CONGRESS.

THIS Congress, which was organised by the British Social Hygiene Council, was formally opened on July 8th, at Livingstone Hall, Broadway, S.W. 1, by Lord Linlithgow, assisted by Mr. Wedgwood Benn, Secretary of State for India, Mr. A. A. W. H. Ponsonby, for the Dominions Office, the Hon. Sir. Atul Chatterjee, High Commissioner for India, Dr. C. L. Park, representing the High Commissioner for Australia, and Dr. Bernard Myers, representing the High Commissioner for New Zealand.

The League of Red Cross Societies was represented by Dr. C. Lillingston, the Admiralty by Surgeon-Commander Rivaz, and Surgeon-Captain T. B. Shaw, the Air Ministry by Squadron-Leader H. S. C. Starkey, the Board of Education by Dr. R. H. Crowley, the Colonial Office by Dr. D. H. Owen, the Ministry of Health by Col. L. W. Harrison, the War Office by Major C. F. White, the Department of Health for Scotland by Dr. T. F. Dewar, the Welsh Board of Health by Dr. T. W. Wade, the Government of Northern Ireland by Dr. N. C. Patrick. Australia, Canada, India (31 delegates), New Zealand, S. Africa, Barbados, British Guiana, British Honduras, Ceylon, Cyprus, Fiji, the Gold Coast, Malta, Mauritius, Northern Rhodesia, Seychelles, Southern Rhodesia, Straits Settlements, Tanganyika, Uganda and Zanzibar, were all represented. Mr. N. W. Edson represented the American Social Hygiene Association. Among the home organisations represented were, the British Medical Association (Dr. H. Guy Dain and Mr. N. Bishop Harman), and the Central Council for Health Education (Prof. A. Bostock-Hill and Dr. J. Robert Kaye). Many Universities and towns had sent their own representatives.

Reviewing the work of the League of Nations and of the Advisory committee in relation to prostitution, on July 8th, Dame **RACHEL CROWDY**, Chief of the Social Questions Section of the League of Nations, gave an account of the international situation with regard to the venereal diseases. Her conclusion was, the advocates of attacking the problem of prostitution from the old angle of control and regulation were losing ground every day. Certain countries are introducing, through compulsory treatment, a new kind of regulation, while other countries are ensuring the complete freedom of treatment. It was for the public to choose between the two. The work of the League of Nations in connection with venereal disease was described by Sir George Buchanan and Col. L. W. Harrison, and the work of the International Labour Office in social hygiene by Mr. H. B. Butler.

Venereal Disease in the Navy.

At the afternoon session, Mr. E. B. **TURNER** in the chair, Surgeon-Commander P. M. **RIVAZ** described the preventive measures taken against venereal disease in the Navy. He pointed out that, during recent years, there has been a considerable decline in the incidence of all forms of venereal disease, the North American, West Indian and African Stations being exceptions. He added that, as a rule, the further a sailor get from home, the more he is liable to contract venereal disease. Most countries visited by the British Navy have licensed brothels under medical supervision which is apt to be carried out in a perfunctory manner. There is very little disease contracted in Malta itself, in contradistinction to the relatively high rate of many other Mediterranean ports. With regard to control, he described the strictly confidential venereal case sheet which follows a man from ship to ship. On it full details as to progress and recommendations as to further treatment are noted. This enables medical officers to ensure that the syphilitic patient, who is half way through his course does nor get overlooked and that the man with a chronic discharge is properly supervised. Men suffering from venereal disease can only be drafted to ships carrying a medical officer. He had been asked to produce some statistics bearing on the efficiency of prophylactic treatment in the Navy, but, though he did offer some figures, he was inclined to regard them as of very doubful value. However, he believed them to show that early disinfection is of value. One of the chief causes of the decline of venereal disease in the Navy was, in his opinion, the lowered alcohol consumption. He had ascertained that, at one large shore establishment, only 28 per cent. of the men drew their rum ration—an indication of the temperance and sobriety of the present-day blue-jacket.

Squadron-Leader H. S. C. **STARKEY**, representing the Air Ministry, made a brief statement with regard to venereal disease in the Air Force, and Admiral Sir **REGINALD TUPPER** gave a comprehensive survey of what has been and is being done for the British Merchant Service at home and abroad. Among those who took part in the subsequent discussion was Fleet-Surgeon W. E. **HOME**, whose remarks clearly showed how much there still remains to be done for the merchant seamen.

Administrative Control in Scotland.

On July 9th, Prof. A. Bostock-Hill in the chair, Dr. T. F. **DEWAR**, Medical Officer of the Scottish Board of Health, read a paper on the administrative control of the venereal diseases in Scotland. He said that, even to-day, only a relatively small proportion of the cases of venereal disease, whether syphilis or gonorrhœa, receive early, efficient and adequate, or sufficiently prolonged treatment. He was inclined to throw some of the blame for this state of affairs on the medical profession, and to overcome this evil, he said "there seems no measure except to secure that every medical graduate shall have had adequate training in the diagnosis and treatment of the venereal diseases." He gave the following statistics for the years ended May, 1922, and May, 1928, respectively:

In 1921–22 the total number of patients attending the various clinics in Scotland was 22,898. The number of new patients was 12,542, and the total number of attendances was 262,643. In 1927-28, the corresponding figures were 27,259—16,032—and 442,807, respectively.

Dr. **DEWAR** also said that there is a general opinion that the incidence of syphilis, as revealed by the attendance of cases alike in early and late stages, has steadily tended to fall from the years 1918 or 1920 to about 1926. Since then it is believed that, for some unknown reason, there has been an increase in the prevalence of this disease. Ophthalmia neonatorum has been so vigorously dealt with in Scotland that, in the last seven years, only ten children have lost all useful vision from this cause. Taking part in the subsequent discussion, Dr. **DEWAR** assured his listeners that, were Scotland to be given facilities for compulsory measures, those who had to carry them out would take very good care that they were not abused.

The diagnosis and treatment of venereal disease in Wales was the subject of a paper by Dr. T. W. **WADE**, Medical Officer of the Welsh Board of Health, and the problem of venereal disease in Australia was dealt with by Dr. C. L. **PARK**, Chief Medical Officer, Australia House. A summary of the venereal disease problem had also been prepared by the Australian Association for fighting venereal disease.

Disinfectant Packets.

In the course of the discussion some interesting figures were quoted by Mrs. C. **NEVILLE ROLFE** in connexion with the suggestion that the disinfectant packets served out to men in the Army and Navy are of a certain value in preventing venereal disease. These figures, which were compiled by Dr. Querat, and published in *Bulletin de la Société Française de Prophylaxie Sanitaire et Morale* for July, 1927, were quoted by Mrs. Rolfe "for what they were worth." The French

Army authorities started a mass experiment in 1921, the men of five Army Corps being provided with prophylactic packets, while the men of five other Army Corps were not thus equipped, the conditions being, otherwise, approximately similar. In the Army Corps provided with packets, the incidence of gonorrhœa was reduced from 10·92 per thousand to 7·51—a reduction of 3·41. But, in the case of the Army Corps not thus equipped, the incidence of gonorrhœa per thousand was reduced from 18·70 to 10·30—a reduction of 8·40. A similar difference in favour of the men not provided with packets was observed in the case of syphilis.

Venereal Disease in British Guiana.

During the afternoon Session, Mr. L. S. AMERY, M.P. in the Chair, a paper was read by Dr. B. N. V. BAILEY on venereal disease in British Guiana. As a result of his experience in this country, he was averse from compulsory measures. Of the 13,000 in-patients treated in the Georgetown Hospital during 1927, 915 were reported as suffering from one or other of the venereal diseases, while, of 27,000 out-patients, over 2,000 were so diagnosed, or approximately 8 per cent. of the total number of cases treated. Of the in-patients at the Georgetown Hospital in 1927, as many as 760 suffered from syphilis and only 42 from gonorrhœa. He commented on the remarkable infrequency of organic nervous disease due to syphilis, and he suggested that, in a country where malaria is so profoundly endemic, this disease might have some influence on the development of syphilis of the central nervous system.

Dr. R. E. HOPTON gave an account of the organisation of the anti-venereal disease campaign in Cyprus. He was sent there in 1927 as a venereal disease specialist, and now has the assistance of a fully qualified English bacteriologist.

False Names and Addresses.

During the morning session on July 10th, Mr. SOMERVILLE HASTINGS, M.P., in the Chair, Col. L. W. HARRISON produced some statistics dealing with the frequency with which the patients attending the male section of his department at St. Thomas's Hospital gave false names and addresses. Of 4950 follow-up letters sent to patients on first default in the five-year period, 1924–28, 1280, or between 25 per cent. and 26 per cent. were returned through the Dead Letter Office. Except for 1924, when the percentage was 21, the proportions were very constant, varying only between 26 per cent. and 28 per cent. The percentage of the patients who resumed attendance as a result of this first letter was between 23 per cent. and 24 per cent. and just under 9 per cent. wrote and explained their absence. Of the large remainder of between 42 per cent. and 43 per cent. who did not reply or resume attendance at once, many eventually resumed attendance. In the female section of his department false names and addresses were given very rarely. Discussing the comparative merits of a venereal disease centre, inside or outside of a general hospital, he was inclined to think that this question was subordinate to that of the personality of the staff of such a centre and he remarked on the devastating efficiency with which an unsympathetic member of the staff could empty such a centre. He described in some detail the attractions which he had encouraged in order to make patients less clinic-shy. In the discussion which followed this paper, a speaker from Scotland tempered his praise of Col. Harrison's paper with the suggestion that the compulsory measures which many of the authorities in Scotland would like to see introduced, were, in the long run, likely to prove more effective than the blandishments with which venereal disease workers in England were trying to keep their patients under continuous medical supervision. Answering these and other criticisms, Col. Harrison apologised for having introduced the subject of compulsory versus free treatment, but he confessed to being still an unrepentant advocate of gentle moral suasion, without draconic measures.

Some Figures from India.

In a paper on the venereal diseases in the United Provinces (India), Dr. A. B. SOUSA said that Col. H. Stott had, for one year, carried out the Wassermann test on all the patients coming to the Kasauli Institute for treatment for dog-bite, and had found it positive in about 22 per cent. The incidence of syphilis and gonorrhœa in the adult population of Lucknow was approximately 20 per cent., whereas it was uncommon in the rural areas. While the incidence per thousand of all forms of venereal disease in the Indian troops in Lucknow had fallen from 99 in 1926 to 85 in 1928, the corresponding figures for the British troops in the same area were 160 and 66 respectively—a very much greater decline.

Conclusion.

This Congress has served many useful purposes. It has brought together many of the men who, during the last few years have taken out post-graduate courses, formal or informal, and have carried out and sometimes modified, according to circumstances, in different parts of the world, the system which has been organised at home under Col. Harrison. Many tributes were paid to the British system by those who have attempted to follow its main principles in other lands. The question of the comparative merits of compulsion and freedom was in the air most of the time, and it is probable that many of the delegates have left the Congress with the impression that the choice between the two systems must largely depend on geographical and ethnical factors. In defining the policy of the British Social Hygiene Council, Mrs. NEVILLE ROLFE pointed out that it tries to give expression to the wishes of its constituents, without imposing any arbitrary or oligarchical policy.

THE NATIONAL INSTITUTE FOR THE DEAF.

THE fifth annual meeting of the National Institute for the Deaf was held at the Caxton Hall, Westminster, on July 11th, when Lord Charnwood, the President, occupied the chair. He was supported by Mr. Somerville Hastings, M.P., and Sir Frank Benson. There was a large attendance.

Before the report of the Committee and the accounts for the year were submitted to the meeting for approval, Mr. A. J. Story, the secretary, summarised the history of the National Institute for the Deaf. It commenced its activities, he said, four years ago, before which time, although there were a number of local organisations for promoting the welfare of the deaf, there was no central body whose concern it was to watch over the interests of the deaf and the deafened. The Committee felt that the time had now arrived in the social history of the country to place the case of the deaf persons before the public, taking note of the intellectual, social, industrial, and religious questions which constituted a great problem. There were many indications, he said, that the national conscience was awakening to the gravity of deafness, both as it affected those who suffered from it and the economic interests of the country. The estimate had been made that the annual loss caused by deafness in this country amounted to £7,000,000. An important feature of the report was a reference to the work of the Committee in devising methods for safeguarding the deafened against the disappointment and loss involved in dealing with firms whose only apparent concern for deafness was the extent of their sales. It had been decided to maintain a register of firms and dealers who had agreed to the conditions:—

(1) That each client will be advised on the merits of his case as to whether an electrical or mechanical or no instrument at all is likely to help;

(2) That, in the event of a client being dissatisfied with the performance of the instrument supplied, the firm or dealer will refund the purchase money, less

10*s.* 6*d.* to cover expenses, if the instrument is returned in good order and condition within four weeks and;

(3) That no call will be made at the home of an inquirer unless at his request;

A number of reliable firms and dealers who conduct their business on these fair conditions had coöperated with the Committee, and no doubt others would be willing to add their names to the register. Deafened persons were strongly advised in their own interests to treat only with those firms and dealers who had agreed to the conditions, and lists would be sent to any inquirer on receipt of postage.

Mr. W. G. Yates the hon. treasurer, submitted the report and accounts for the year 1928-29, stating that although the Committee were able to meet their expenditure during the year, there was only a small balance of £221, so that anxiety was felt regarding current income, which was entirely inadequate to the needs. [The document, which was in circulation in the room, dealt in detail with the work of the Institute and the national organisation of welfare work, reviewed the social and industrial position of the deaf and deafened, and emphasised the imperative need for Government inquiry. A large portion of the report was devoted to the serious matter of the commencing as well as of the higher education of the deaf and the training of teachers of lip-reading. It can be obtained from the Office of the National Institute for the Deaf, 2, Bloomsbury-street, London, W.C.]

Lord Charnwood then moved the adoption of the report and accounts, and referred to the efforts which he had made in the House of Lords, supported by the Duke of Montrose and others, to induce the Government to set up a body for inquiry into the position of the deaf. Although the attitude of the Government at that time was unsympathetic, he hoped that the future would be more promising.

Mr. M. Birley, chairman of the Executive Committee, seconded the adoption of the motion; which was unanimously carried.

Mr. Somerville Hastings, M.P., aural surgeon to the Middlesex Hospital, moved:—

> "That having regard to the grave social and industrial hardships caused by deafness in the lives of large numbers of adolescent and adult persons who were born deaf or have become so, and to the fact that no official inquiry into the results (in the terms of improved social and industrial well-being) of large public expenditures in their education has ever been held, this meeting is strongly of opinion that the time has arrived when a complete investigation into the conditions and needs of these deaf and dumb and deafened persons should be made; and, further, that this meeting urgently calls upon the Government to make such an investigation by means of a Departmental Committee, or otherwise, at an early date."

He said that the inquiry into the condition of the deaf was urgently needed and that the right and proper body to make that inquiry was the Government of the country. The question was sometimes asked as to which was the most unfortunate individual, the *wholly* blind or *wholly* deaf. He would not attempt to make a decision, but he was quite sure that the person who was *almost* blind was much less to be pitied than the person who was *almost* deaf. The person who was almost blind could see just enough light to get about without assistance, but the person who was almost deaf was shut off from his friends. There was a peculiar psychology associated with deafness which, apart from the deficiency of hearing, was provocative of much sympathy. The sensation of hearing was, perhaps, evolved by the necessity of the animal to protect itself against its enemies, and the person who lacked that sense lacked a primitive function. There was therefore little surprise, granting the truth of that theory, that the deaf person was very liable to be introspective, to shun his fellows, to be shy and to be morose. Knowing this, a good many of those who, like himself, had to deal with the deaf professionally, advised them to cultivate more than anything else "cheek"—to be pushful. The deaf, particularly the industrial deaf, were handicapped by lack of the qualities of self-assertion throughout their industrial lives. The employer was afraid that the deaf would be more liable to accidents, and he instanced a case which had recently come before his notice in which a skilled engineer had been compelled to take a job as a labourer by reason of becoming deaf, and not only was his work affected, but his consequent moroseness had blighted the amenities of an otherwise happy home. It should be remembered, too, that no one was free from the possibility of becoming deaf. Therefore the condition of the deaf man or woman was one that needed special care, and it was time that the State took notice of the matter. A large proportion of deafness among children was due to middle-ear disease, and, while a good deal of that could be prevented, the State was not doing all that it might do for those below school age. Although the State did do something for the congenitally deaf child, care started too late, as the early years of education were all important—this criticism, he said, did not apply to Scotland. He would like to see complete deafness in children made a notifiable disease, so that the State could know exactly who were the deaf and would be able to deal with them sensibly. As for the adult deaf, the State did nothing for them, and those who had the matter at heart should demand the Government to make an investigation into the condition of the deaf generally, by means of a Departmental Committee or otherwise.

Sir Frank Benson, who seconded, made an earnest plea for sympathy and help for the deaf, a word which he said implied a tragedy. Everything that delayed action and communication of thought delayed the progress of the people and the welfare of the State, and it was up to everybody to see that no efforts suffered from slackness.

The resolution was supported by Mr. Hugh Morrison and carried unanimously.

On the motion of Lady Charnwood, seconded by a member of the audience, the thanks of the meeting were given to those who had served during the past year on the Executive Committee, and the following were elected for the ensuing year: Rev. F. W. G. Gilby and Rev. A. Smith; Sir Harry Stephen; Col. H. S. Ravenhill, C.M.G.; Major F. J. Wegg Prosser; Dr. Chas. Heath and Dr. D. A. H. Moses; Misses H. Davids; M. Hare, B. Nevile, and F. M. Townsend; The Hon. Mrs. John Tennant; Messrs. E. Ayliffe, H. J. Gibbons, W. McDougall, C. F. Mott, S. A. N. Oxley, L. B. Phillips, C. Shaw, and A. W. Taylor.

A vote of thanks to the Chairman terminated the proceedings.

MENTALLY DEFECTIVE ADULTS.

THE QUESTION OF STERILISATION.

IN the first instalment[1] of their report the Joint Committee of the Board of Education and the Board of Control discussed briefly the extent to which sterilisation of mentally defective adults in the present generation would reduce the volume of mental deficiency in the next, and came to the conclusion that, even if this measure were rigidly applied to all the mentally defective, the reduction would not be great. The last instalment[2] considers a more cogent ground for advocating sterilisation, namely, that its application would ease the economic burden by enabling defectives who would otherwise have to be permanently segregated in institutions to return to the community with no risk of their becoming parents, and that a number of them could live happily and harmoniously outside institutions. If it could be proved, say the Committee, that sterilisation could safely and profitably be applied even to certain groups or categories of defectives, the question of its adoption would no doubt deserve careful attention.

---

[1] Report of the Mental Deficiency Committee. Parts I. and II. H.M. Stationery Office. 2*s.*

[2] Same Report. Part III. 1*s.* 6*d.*

American Experience.

The advocates of sterilisation maintain that the method is successfully applied in America. Sterilisation laws have been passed in about twenty American States, and more recently in Alberta, Sweden, and Switzerland; but only in two American States have these laws been enforced on any considerable scale. The reasons generally given by those who have studied the problem in America for the failure to enforce these laws in those States in which they have been enacted, are that public opinion has apparently disapproved of sterilisation on humanitarian grounds: that the question of doubt as to diagnosis and prognosis and the difficulty of drawing the fine line of demarcation between those who should and those who should not be deprived of the power of propagation appear to have served as deterrents in making the decision on a concrete case: that many well-informed persons have opposed sterilisation as tending towards the spread of immorality and venereal disease by giving liberty to the individual together with the assurance of immunity from pregnancy and its consequences; and that the general aspects of the relation of heredity to mental deficiency have served to raise doubt as to how much may be gained by sterilisation.

The evidence available in regard to the results achieved in California, where the first sterilisation law was passed in 1909, is far from conclusive. So far as it goes it tends to show that sterilisation has only enabled a small proportion of the defectives to be discharged from institutions. A failure of first efforts in this direction need not, however, surprise us, and further experiments should be sympathetically watched. The Committee are not prepared to deny that this measure might, under adequate safeguards prove of value in a very limited number of individual cases seleced from among the more stable type of defective with no anti-social tendencies, though they cannot disguise from themselves the serious difficulties that would arise in restricting sterilisation to this particular type of case. They feel, however, that there is not sufficient evidence at present to justify the general adoption of sterilisation of defectives, and are convinced that, even if it were adopted, no great alleviation of the burden of mental deficiency would follow.

Three Grounds for Hesitation.

In the first place, in the Committee's view, sterilisation would not reduce to any appreciable extent the numbers of defectives already in institutions, since the large majority of these have been admitted and are retained because they are urgently in need of the care and protection which institutions alone can give. The sterilisation of the mentally defective adult is advocated by some persons as an alternative to what they regard as the more expensive method of segregation. Their assumption is that large numbers of mental defectives who are now retained in our institutions would be capable, if sterilised, of maintaining themselves economically, or at least of living harmoniously outside the institution. The consensus of opinion however amongst those who best know the practical capacities and the temperamental features of the patients who are at present in colonies and institutions, is that comparatively few of them would be fit to be restored permanently to live in the community. Sterilisation does not make defectives more stable, does not enable them to earn their living, does not prevent them from getting into mischief, and does not enhance their social efficiency in any way; it may, indeed, increase their moral danger, and prove injurious to the health of the community.

In the second place the sterilisation of a few individual cases, if legal sanction for this could be obtained would not appreciably, if at all, reduce the urgent need for a large increase in institutional accommodation. The Committee regard with much apprehension the tendency observed in some quarters to allow the discussion of this question and the hope of legislation on the subject, to retard the provision of the institutional accommodation which is so lamentably insufficient in all parts of the country. The cases to which sterilisation could profitably be applied are not among those for whom this additional accommodation is required, for it must be borne in mind that large numbers of defectives are not socially adjustable and should not be left in the community in any circumstances, while many of those who might ultimately be returned to the community would first require a long period of training and stabilisation to fit them for life outside an institution. Moreover, the view of many who have had wide experience of mental defectives in this country is that the freedom accompanying sterilisation, though it might increase the happiness of some defectives, would be positively harmful to many others.

In the third place the Committee believe that the legalisation of this measure, however carefully safeguarded, would inevitably greatly enhance the difficulties of bringing defectives within the scope of the Mental Deficiency Acts. The parent would be less likely to apply for the protection of the Acts to be extended to his defective child, the certifying officer would be more reluctant to issue his certificate, and the magistrate would be less willing to make an order, if it were known that such action on the part of each of them might render the defective liable to be sterilised.

Personnel of the Committee.

The names of those who have thus given their considered opinion on the merit of sterilisation as a practical method of dealing with mental defects in the adult, are: Mr. Arthur H. Wood, late Assistant Secretary, Medical Branch, Board of Education (*Chairman*); Dr. Ralph H. Crowley, Senior Medical Officer, Board of Education (*Vice-Chairman*); Mr. Cyril L. Burt, Psychologist, London County Council; Mr. Cecil Eaton Assistant Secretary, Medical Branch, Board of Education; Miss Evelyn Fox, Hon. Secretary, Central Association for Mental Welfare; Mrs. Hume Pinsent, Commissioner, Board of Control; Miss Hilda Redfern, Head Mistress, Monyhull Colony School for Mentally Defective Children.; Dr. Frank C. Shrubsall, Senior Medical Officer, London County Council; Dr. Alfred F. Tredgold, Lecturer in Mental Deficiency, London University; Dr. F. Douglas Turner, Medical Superintendent, Royal Eastern Counties Institution, Colchester; and Mr. N. D. Bosworth Smith, Principal, Medical Branch, Board of Education (*Secretary*).

PAY BEDS IN LONDON HOSPITALS.

The number of pay beds at voluntary hospitals in London is now 1154 distributed over 88 hospitals. The charges are usually about four to six guineas a week, exclusive of certain extras and of medical and surgical fees, though, at either end of the scale, there are a few beds for the well-to-do and some for those in straitened circumstances.

A complete list of the beds available at hospitals making returns to King Edward's Hospital Fund has been prepared and is obtainable for 6d. from the offices of the Fund at 7, Walbrook, London, E.C.4. For the convenience of our readers, we set out below a list of the hospitals which have pay beds, the number of beds and the normal weekly charges. This charge does not include any medical or surgical fees that may also be payable. In nearly every case one or more of the following specific services, if required, are charged for as extras, sometimes as an addition to the hospital charge, sometimes as part of the medical fee, viz.: Anæsthetist; exceptionally expensive drugs and/or dressings; electrical treatment; light treatment; massage; extra nurses; operating theatre; pathological examinations; radium; X ray.

For a description of the type of accommodation available (cubicles, wards with more than one bed, single rooms) and the number of beds allocated to either sex the list must be consulted.

Watford.

Dr. W. J. Cox says that the two chief public health questions of his borough are housing and the provision of public baths. During 1928 435 subsidy houses were erected, 24 by the local authority and 411 by private enterprise. There is much overcrowding in the smaller houses and the decision of the council to build another 110 houses is well-timed. The closing and demolition of 139 houses during the last four years has made the slum question in Watford much less evident. There are 700 families on the waiting-list for houses and 30 new houses are needed to replace houses which ought to be demolished. The supervision of the watercress beds is being continued, although none was closed in 1928 as compared with three in 1927. Dr. Cox points out that the existence of watercress beds in thickly populated urban districts is not desirable, but that in a rural district it is a different matter, if the cress beds can be provided with a pure water-supply and are so situated that the general public has no access to them. The Red Cross orthopædic centre did valuable work and a list is given describing the nature of the 58 cases referred to the clinic, which is conducted by Mr. S. L. Higgs, F.R.C.S.

The isolation and small-pox hospitals serve a population of about 40,000 in the surrounding district in addition to the residents of Watford. Watford is growing rapidly and Dr. Cox thinks 100 beds are needed instead of the 66 at present provided. The small-pox hospital was opened twice. Between Feb. 3rd and Feb. 11th three "casuals" were admitted from the workhouse, each of whom had contracted small-pox in quite different parts of the country. On May 29th another "casual" was admitted, by whom a Watford resident was infected. A proposal to pool the small-pox accommodation in the county did not meet with the approval of the management of the joint hospitals, it being held that Watford might suffer if it had to provide small-pox accommodation for a larger district than at present.

Torquay.

Dr. Thomas Dunlop says the opening of the New Torbay hospital with its up-to-date maternity wards has met a much-felt want. The maternity ward has eight beds and arrangements have been made by the council for the admission of necessitous cases. A separate antenatal clinic is to be established at the hospital. The clearing of the Pimlico insanitary area has reached its final stage, but there are still certain properties on the area which are not insanitary, but are essential to the scheme and which will have to be acquired by arbitration. The gathering ground of the water-supply is being extended and it is expected that the new source of supply will be available during the summer of the present year. The gathering ground is on the borders of Dartmoor and the water, although soft, contains sufficient lime and magnesia to prevent any solvent action on lead. Housing remains a difficult problem and there are still a large number of applicants living under bad conditions. The new houses erected numbered 198, of which only 20 were subsidy houses, all municipal. A vita-glass sun lounge has been erected by the council as an adjunct to the medical baths. The record kept of the results of the acetone methylene-blue tests shows that Torquay is high up among the places keeping such records, and the hours of bright sunshine numbered 1845·6.

Tunbridge Wells.

Dr. F. C. Linton says that one patient was admitted to the small-pox hospital, which serves Tunbridge Wells and the surrounding districts, and made a good recovery. There is an increasing demand for the beds at the maternity home, which is a "voluntary" institution, serving the surrounding district. Ninety-four of the patients admitted were Tunbridge Wells residents, for nine of whom the corporation paid the fees according to agreement. The question of the extension of the home is now under consideration. For half the year Tunbridge Wells is supplied with water from springs in the Tunbridge Wells sandstone. During the remainder of the year this supply is supplemented by artesian wells bored through the Wadhurst clay to the Ashdown sand. Until the dry season of 1921 these two sources were adequate, but at the present time the work for a further supply, by boring down to the Ashdown sand in another position, is in hand. The number of new houses erected was 94, of which 34 were municipal and nine private enterprise subsidy houses. The construction of an open-air school was to have been begun in the autumn of 1928, but at the last moment the site was discarded and a search is being made for a new site with more advantages. In the meantime voluntary workers are making provision for some of the delicate children who need an open-air school. The work of the aural clinic for the school-children, which is held at the Eye and Ear Hospital, shows a large increase and on April 1st an orthopædic clinic was established at the General Hospital under the auspices of the education authority. The rainfall, about 34 inches, exceeded the average, largely owing to a fall of seven inches in October. The 1810 hours 18 minutes of bright sunshine made Tunbridge Wells an easy first for sunshine amongst the inland health resorts.

Chelmsford.

Dr. Richard H. Vercoe reports that at the end of the year the scheme to obtain water from the river Chelmer was nearly completed. The treatment tanks are divided into nine compartments. Sulphate of alumina solution and lime-water are added at the point of entry and carbonic acid gas is diffused in the water in the penultimate compartment. After storage the treated water is pumped through Paterson pressure filters to the service reservoir, chlorine gas being added to the water both, before and after filtration. There is a well-equipped laboratory, where constant tests will be made by a resident chemist. There are a large number of houses in Chelmsford which are constantly in need of repairs to keep them fit for human habitation, and in some cases demolition is the only satisfactory remedy. About 50 are only fit for demolition; and 300 more need regular repairs. On the municipal estate 62 houses were completed during the year and 56 are contracted for. An antenatal clinic was held monthly at the Chelmsford Hospital and attended by 34 expectant mothers. The report of the veterinary inspector, Mr. W. Mulvey, states that all the cows and cowsheds are inspected at least once in every two months. The sheds number 11 and the cow population is about 250. Twenty-two cows were removed from the cowsheds during the year and 20 cows tested with tuberculin.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED JULY 6TH, 1929.

Notifications.—The following cases of infectious disease were notified during the week: Small-pox, 153 (last week 160); scarlet fever, 1898; diphtheria, 000; enteric fever, 44; pneumonia, 909; puerperal fever, 40; puerperal pyrexia, 98; cerebro-spinal fever, 12; acute poliomyelitis, 7; encephalitis lethargica, 22; continued fever, 1; dysentery, 14; ophthalmia neonatorum, 115. No case of cholera, plague or typhus fever was notified during the week.

The number of cases in the Infectious Hospitals of the Metropolitan Asylums Board on July 9th-10th was as follows: Small-pox, 200 under treatment, 6 under observation (last week 190 and 8 respectively); scarlet fever, 1820; diphtheria, 1660; enteric fever, 8; measles, 231; whooping-cough, 487; puerperal fever, 28 (plus 9 babies); encephalitis lethargica, 124; "other diseases," 80. At St. Margaret's Hospital there were 18 babies (plus 9 mothers) with ophthalmia neonatorum.

Deaths.—In the aggregate of great towns, including London, there was one death from small-pox, 5 (1) from enteric fever, 42 (8) from measles, 5 (0) from scarlet fever, 30 (8) from whooping-cough, 16 (7) from diphtheria, 48 (7) from diarrhœa and enteritis under two years, and 25 (5) from influenza. The figures in parentheses are those for London itself.

The single death provisionally classified to small-pox was assigned to Stepney. Liverpool reported 12 deaths from measles, Wallasey, Salford and Leeds each 3. Three deaths from whooping cough occurred at Sheffield. The highest figures for diarrhœa were Birmingham and Liverpool each 8, Manchester 5, Nottingham, Warrington and Salford each 3.

The number of stillbirths reported during the week was 270 (corresponding to a rate of 40 per 1000 births), including 40 in London.

RESEARCH IN THE BREWING INDUSTRY.

MANY industries in this country have been carried on for hundreds, or in some cases for thousands, of years on purely empirical lines, and it is only since the later decades of the nineteenth century that science, with its exact knowledge based upon definite facts, has intervened to displace gradually the former universal rule-of-thumb methods. Even now there are business men who consider science of little value apart from its immediate application to their own problems and the production of increased profits. They do not realise that "Science moves but slowly, slowly creeping on from point to point." But the industrialist does appreciate the value of a sound knowledge of fundamental principles, and the 1929 Memorandum of the Research Scheme of the Institute of Brewing is a good illustration of this fact. This memorandum summarises a number of investigations carried out under the ægis of the Research Committee, many of them in collaboration with other bodies. They include the production of new varieties of barley and hops, the effects of various agricultural conditions, chemicals and biological methods for the evaluation of hops and methods of defence against their field parasites, and the utilisation of the nitrogenous constituents of wort by yeast. The magnitude of the undertaking may be realised when it is considered that the whole of the factors under investigation, from the breeding of the barley and hops, must be correlated singly and in conjunction with the qualities of the finished beer. The Research Scheme is administered by a committee in conjunction with various advisory sub-committees, the members of which are representative of all branches of the brewing industry, together with botanists, chemists, bio-chemists and growers of barley and hops. Team work of this kind may well have results of value outside the brewing trade, in which it is not forgotten that the brilliant bacteriological researches of Pasteur, when applied by Lister, revolutionised the practice of surgery.

THE DEVELOPMENT OF PULMONARY TUBERCULOSIS.

To the Editor of THE LANCET.

SIR,—Dr. H. V. Morlock's paper in your last issue will be welcomed by many as throwing considerable light on that somewhat "elusive Pimpernel," the early case of pulmonary tuberculosis. The tuberculosis officer, no doubt, sees, or should see, most of the cases in his district, but it is an unfortunate fact that the number of early cases examined are few and far between. I feel however that they do, if discovered, conform to the description given by Morlock, and quote the following two cases as examples.

1. A. B., female, aged 26, was well until Christmas, 1928, when she had an attack of pyrexia with cough. On examination in January, 1929, her general condition was good and no signs detected. The cough continued with pyrexia and in April, at the onset of expectoration, her sputum was positive, crepitations were heard below the left clavicle and at the left apex behind, and an X ray photograph showed a triangular opacity just below the left clavicle, with the base against the ribs and an appearance of cavitation.

2. C. D., female, aged 18, had, as it happened, been under close medical supervision. In July, 1928, her weight was 8 st. 5¼ lbs., her general condition very good and she had no physical signs. In December, 1928, her weight had increased to 8 st. 7¼ lbs., her general condition was still good with no physical signs, but she complained of an irritable cough and her temperature was 99·2° F. In February, 1929, her weight had fallen to 8 st. 2¼ lbs. Crepitations were now heard below the right clavicle, but not behind. Her sputum, when examined at the onset of expectoration, was positive on three consecutive days, and X rays showed an area of infiltration, proceeding to cavitation in the right subclavicular region.

The above type of case, as already stated, is not often seen, for in the majority of cases, the tuberculosis officer is called in at a later date, when the infiltration has already spread upwards and downwards into the rest of the lung. I have myself been struck with the frequency with which patients state that they first consulted their doctor "some months ago" and were told that they were suffering with "influenza." This point is of great importance, and is brought out by Morlock in his paper. When diagnosing a sudden febrile attack as "influenza," the general practitioner should bear in mind the possibility that the case may be one of early tubercle, and although there may be no physical signs, he is fully justified in sending such a case for further investigation to the tuberculosis officer, who should have at his disposal complete facilities for X ray examination.

The particulars of another case show the disasters which may readily occur, if we do not orientate our minds to this new conception of phthisis with its acute onset and rapid progress.

3. E. F., female, aged 20, used to sleep in the same room as her sister A. F., who died of advanced pulmonary tuberculosis at Christmas, 1927. E. F. was examined as a contact in January and June, 1928, and was found to be in good condition with no physical signs. She remained under the care of her doctor, and in November last was sent to the throat department of a London general hospital for a sore throat. She was kept there for out-patient treatment and in January referred to a physician of the hospital for an opinion on her chest. No physical signs were found and she was given a clean bill of health but was unfortunately not X rayed. In May her own doctor suspected pulmonary tuberculosis, and she went away to a convalescent home. In June I was asked to see her and found an advanced case of tuberculosis with extensive signs in both lungs, any form of treatment being hopeless. The sputum was positive.

We must consider, if we intend to accept the views of Morlock and of continental workers, where they lead us. A consideration of contact examination in the tuberculosis of infancy, together with the post-mortem findings of Küss, Ghon and Aschoff, and Armand-Delille and Lestocquoy, cannot but lead one to believe that in infancy tuberculosis is a true infective disease, spread directly from one person to another. It may be that the latest work on the development of pulmonary tuberculosis in the adult will lead us in the same direction, *i.e.*, that in the adult the disease is spread in the same way. Such a theory will shatter many of the tenets of our forebears, but inasmuch as it may lead to a study of the disease on more scientific lines, and perhaps to a discovery of more early cases, it deserves our consideration.

I am, Sir, yours faithfully,

C. H. C. TOUSSAINT,
Tuberculosis Officer, Bermondsey.

Grange-road, Bermondsey, S.E., July 16th, 1929.

LOSS OF APPETITE IN CHILDHOOD.

To the Editor of THE LANCET.

SIR,—Your comments on Dr. Garland's article and Prof. Mottram's letter on the same topic prompt me to say a word regarding the importance of educating the human palate from early years to appreciate and enjoy the right kind of food, and of not allowing natural healthy instincts to be spoilt by indulgence in tasty luxurious foods. A child brought up in the country on simple healthy food, and having the run of a well-stocked kitchen garden, displays an instinctive delight, not only in fruit, but in such vegetable produce as young peas, carrots, onions, and lettuce. Why do we not take this hint and encourage children from quite an early age to cultivate their natural taste for these healthy foods? The wide range of adaptability of the youthful palate is shown by the ready way in which children of every country take to the national diet.

A word regarding sugar in the present connexion. Sugar is a good food from the point of view of nutriment, but unless given cautiously it is a bad food for children, in that it is apt to spoil the palate for simple healthy food. It is not a necessary food in the pure form; children can get all the sugar they need from starchy foods and fruit. Our ancestors reached the full status of manhood on a diet from which all pure sugar was excluded save that derived from occasional finds of honey. In Elizabethan times when beef cost three farthings a pound, the price of the same quantity of sugar was twenty shillings, the equivalent of much more of our present money, so that we may be sure the boy Shakespeare got along all right on a diet from which both cane and beet sugar were conspicuously absent.

We shall do well, in considering the value of sugar as a food for children, to beware of the harm it may do in spoiling the palate, and in causing dental caries. I personally am convinced that the conversion of all the sweet-stuff shops in the Kingdom into fruit shops—assuming this were practicable—would lead to a great improvement in the health of our children. It would not be far from the truth to say that the near approach to practically all the elementary schools in London contain sweet-stuff traps, where the children spend their odd coppers. Now they enjoy an added service of ice-cream vendors.

I am, Sir, yours faithfully,

Harley-street, W., July 15th, 1929. HARRY CAMPBELL.

IMPLANTED RADIUM SEEDS.

To the Editor of THE LANCET.

SIR,—Dr. Joseph Muir, of New York city, in his article entitled Radium Treatment by the Implantation of Screened Seeds (THE LANCET, July 6th, p. 7), recommends for the radium treatment of bladder cancer the insertion of seeds through a cystoscope, and for prostatic cancer implantation into the gland only by the perineal route. Both methods, whether emanation or the element is used, I submit, are unsound from the pathological standpoint. On more than one occasion and recently by an article in the *Cancer Review* (July, 1929) I have drawn attention to the necessity of thoroughly exploring the full extent of a bladder neoplasm before adopting radium treatment. With the aid of the cystoscope this is impossible; only digital exploration can ensure this knowledge.

Again, in cancer of the prostate Dr. Muir is advocating a method which I have described[1] and abandoned. Malignant disease of the prostate spreads along lymphatics situated in the fibrous sheath surrounding the vesiculæ seminales. It is useless to attack the prostate only, either from the perineum or the bladder, as I have learnt from an experience extending over 15 years. If any success is to be achieved in the radium treatment of this organ the seeds must be implanted in tissues far beyond the frontiers of the prostate.

I am, Sir, yours faithfully,
A. CLIFFORD MORSON.

Brook-street, Grosvenor-square, W., July 11th, 1929.

SHEWRY v. MAYBURY.

To the Editor of THE LANCET.

SIR,—The letter from a juror in this case, in your issue of July 13th, seems to call for comment on one point—namely, as to the contrast that was noticed between the attitude of the medical witnesses on the two sides.

In this case, I was called to give "expert evidence" on a comparatively small point—viz., the interpretation of the Wassermann test—but it so happened that I was present in Court on and off during almost the whole trial. I had not seen or tested the patient. One would have thought that the fact that two of the medical witnesses for Mr. Shewry were present during the whole time and in constant communication with counsel, whereas those for Dr. Maybury did not adopt this practice, was in favour of the latter. A medical witness is not an advocate.

There is another point. The clinical witnesses for the defence were all of them on the active staff of teaching hospitals, and if they had stayed in Court throughout the trial, which lasted over a week, they would have neglected their most important work of teaching students and ministering to the wants of their hospital patients. Those on the other side had no such obligation.

With the rest of the letter I think most of us who have to give expert evidence would agree, and the profession would surely welcome the trial of cases in which questions of clinical practice and pathology play an important part by judges with medical assessors rather than by jury. Even if the jury system had to be retained, it would be well if the medical opinions in a technical case were presented to them after they had been contracted into a coherent mass. It is the details that worry members of a jury and are apt to lead to confusion, which often results in a prejudiced opinion in a certain type of mind. Even the most lucid summing up by a judge—and I have never heard anything fairer or more lucid than that of the Lord Chief Justice in this case—is apt to fall on ears that have been rendered deaf by reiteration of technical terms. What some members of a jury do not seem to realise, however, is that in adhering to prejudice they are false to the oath that they have taken.—I am, Sir, yours faithfully,

A. KNYVETT GORDON.

Bedford-square, W.C., July 15th, 1929.

To the Editor of THE LANCET.

SIR,—A Juror's Reflections describe in concrete form the lack of method in submitting relevant technical medical evidence to a judge and jury. Four-fifths of the medical *opinion* in this case would never have been given to medical assessors. I was one of the ten medical witnesses! Judges decide on questions of law, juries on questions of fact. Expert opinion and expert evidence should be judged by assessors, on behalf of the Court. Important statements as to the results of arsenic injections into the brain, and as to the value or possibility of skull percussion were made on the one hand and denied on the other. No witness could state he had ever seen a solution of arsenic injected into the brain; one witness only had applied skull percussion to this case.

I submit two things (1) that McEwen, Dr. Alexander Robertson (Glasgow Hospital Reports, 1898), Jullès (Percussion du Crane) may be all wrong in the opinion of a particular witness, but to describe their writings and methods as "magic, not medicine," could only be to influence the jury as counsel for the defence, and is unworthy of our profession. (2) That the effect of injecting a solution of arsenic into the brain could only be judged by the condition it produces in the cellular tissue elsewhere.

We can all agree that it is unfair to prosecute nine years after an alleged act of negligence. There should be a Statute of Limitations. And "expert opinion" given by well-known men should be governed by the strict law of evidence, and not by their professional status. I am, Sir, yours faithfully,

W. B. COSENS.

Oakley-street, S.W., July 14th, 1929.

To the Editor of THE LANCET.

SIR,—In your issue of July 13th "a Juror in the Lord Chief Justice of England's Court" reproduced in full a letter from the *Times* on Technical Evidence. Common juries are credited with common sense, special juries with special sense, for which fees are paid commensurate with the supposed educational standard and common sense of the two classes of jury members. Both classes of jury swear on oath or attest that they will listen to the evidence and upon the sworn evidence of the witnesses called for the plaintiff and defence shall on the law of evidence give their verdict. Sympathy is beyond their ken as a jury and is out of bounds. A jury is on a pedestal far above sentiment and sympathy. Each member has sworn to find his verdict on the evidence before the court.

"Special Juror" is not quite correct in his letter to the *Times*. All trials of necessity must have witnesses on one side and witnesses on the other. The jury have to determine on which side is the weight of evidence. The judge, whether it be a civil or criminal case, analyses the evidence and may or may not direct the jury. It is admitted on all sides that the summing up of the evidence in the case of Shewry v. Maybury was wonderful—the expression of a barrister. The Lord Chief Justice emphasised in his summing up that the jury had sworn to give their verdict on the evidence. It is not correct to say counsel were "labouring among technical terms which they did not always know how to pronounce." On one occasion only did counsel say when reading from an authority: "Then comes two words which I cannot pronounce."

"A Juror" goes on to say: "I was one of the majority in the jury, who were unwilling that after eight years a case should be brought up against Dr. Maybury." Sentiment is here again ruling "A Juror." The Lord Chief Justice so clearly laid down the law with reference to a minor, the law with reference to the statute of limitations, and the law with reference to charges for criminal offences. Contrition has now entered into the soul of "A Juror," when he says: "I now suffer from a distinct feeling that Dr. Maybury did not get justice *on the evidence*." What an admission for a special juryman to make, who, with the other members of the jury has sworn to find a true verdict on the evidence before the court. "A Juror" admits that the jury lamentably failed to carry out their sacred duty and were swayed by sentiment and prejudice. It must certainly be a very uncomfortable feeling when one has not acted up to and upon one's oath. How a letter to

---

[1] British Jour. of Surg., 1915, ii., 302; and 1920, viii., 38.

THE LANCET assuages "A Juror's" conscience may be relegated to metaphysics for a solution.

When "A Juror" mentions that "medical witnesses on one side remained in court and showed sincere interest in the case. Those on the other side appeared, spoke and disappeared like a drilled phalanx. This... was noticed by the jury"—when, I say, such nonsense is written by "A Juror," and such trivialities are taken notice of by members of a jury who have sworn to find a true verdict on the evidence, it is not difficult to understand the answers given by the jury to the questions put by the Lord Chief Justice. There was no "piteous muddle" anywhere in the conduct of the case. If there were a "piteous muddle" it emanated from the jury box. The case was opened high; the plaint having absolutely failed, side issues were embarked upon. Of such tactics the judge said he would have something to say later on, and his summing up expressed his extreme disapproval at the line counsel for the plaintiff had taken in shifting the charge of negligence to one of fraud. The Lord Chief Justice's remarks will ever remain indelibly stamped upon the memories of those who listened to those impressive words of disapproval.

If "A Juror" and the other members had listened attentively to the plaint, the sworn evidence, the cross examination, the speeches of counsel, the summing up of the judge, not forgetting they had sworn to find a verdict upon the evidence given, they would now be happier and wiser, sentiment and prejudice having no place in the finding of their verdict.

I am, Sir, yours faithfully,

LEX.

July 17th, 1929.

CONGRESS OF THE ROYAL SANITARY INSTITUTE.

About 1500 delegates arrived in Sheffield at the beginning of the week to attend the annual congress of the Royal Sanitary Institute. Nine hundred of them, or thereabouts, represented governments at home, in the Dominions and India, or abroad, and the meeting is notable because of the unusually large number of participants from every continent. The business of the Congress is being conducted in six sections—viz., Preventive Medicine, Architecture and Engineering, Maternity and Child Welfare, including School Hygiene, Hygiene of Food, Hygiene in Industry, and Veterinary Hygiene; and there are also seven conferences of special officers. A large congregation assembled for the opening service in the cathedral and listened to a stimulating address from the Bishop of Sheffield. Dr. Burrows traced the extraordinary development of the sanitary conscience since Beaconsfield uttered his famous parody, "Sanitas sanitatum, et omnia sanitas," and referred to many of the pioneers, including Shaftesbury and Charles Kingsley. The public conscience, he said, had become much more assertive in his lifetime and no political party dared treat housing and sanitary matters as if they did not matter. Sanitary reform was now part of Christian duty and had become international in its aims. All this work implied faith that it was God's will that man should improve.

On Monday, July 15th, the Lord Mayor of Sheffield presided over a gathering of 500 at the Congress luncheon. The Bishop of Sheffield in proposing the toast of the Institute, sketched the history of its growth and good work during its 53 years' existence, and made special reference to the international character of its operations. The Chairman of the Council, Mr. Edward Willis, in returning thanks, hoped and thought that the present week would be a memorable one in the history of Sheffield and of the Institute. The Duke of Northumberland, in proposing the toast of the municipality, made special reference to the versatility of the present Lord Mayor and his personal efforts for the welfare of the community.

At the inaugural meeting held at the University, the retiring President, the Duke of Northumberland, inducted his successor, Earl Fitzwilliam, who, in his address, spoke of the extraordinary changes caused in the Sheffield neighbourhood during his lifetime by industrialisation. Instead of scattered hamlets and villages, they had everywhere gigantic colliery undertakings, which made all the more necessary the beneficent activities of bodies such as the Sanitary Institute. Lord Fitzwilliam referred particularly to the need for a better allocation of the available water-supply of the country. A vote of thanks to the President was moved by Sir Arthur Newsholme and supported by Surgeon W. H. Frost (U.S.A.) and the Bishop of Sheffield. who indicated his faith in future progress by the remark that the world would be a much better place to live in when we were all dead and buried.

A delightful function on July 16th was the luncheon given to the delegates from overseas by the Council of the Institute. Dr. Charles Porter presided and welcomed the guests in felicitous terms, which were warmly reciprocated by Colonel Phya Damrong Baedyagun (Siam), who spoke of the great improvement in conditions of life in London during the 25 years interval between his two visits to England, by Sir Henry Barwell (Agent General for South Australia), by Miss Howard (Nova Scotia), by Dr. Mallik (India), by Dr. P. S. Fridericia (Denmark), by Councillor W. H. Port (Johannesburg), who said "the city of sunshine built on gold" was making use of the best of the sanitary experiences of the old country, and by Miss Ellen Babbitt (U.S.A.)

PREVENTIVE MEDICINE IN LONDON.

THE NEW SCHOOL OF HYGIENE AND TROPICAL MEDICINE.

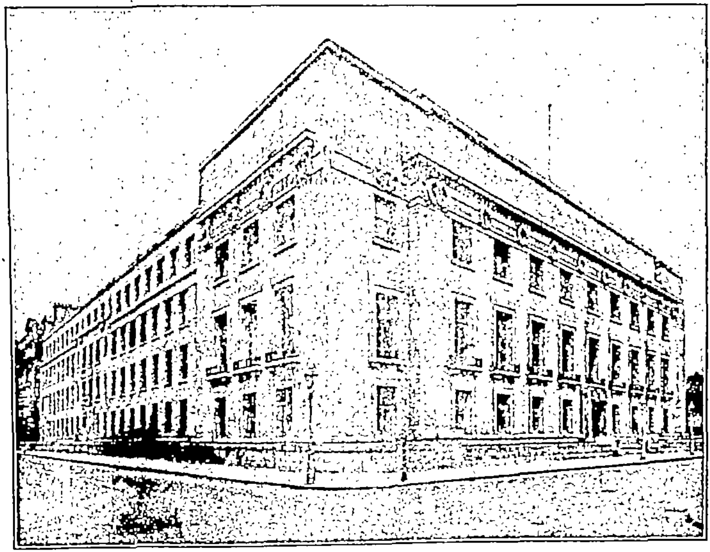
THE great new building opened in London this week is something more than the Institute of State Medicine envisaged by the Athlone Committee of 1921. It will be an international, as well as a national, centre of public health, and its definition of preventive medicine will cover the needs not of this country alone, but of the whole inhabited world.

So wide a view of its functions is justified partly by its constitution, and partly by the way it has come into being. On the one hand, union of the new school of Hygiene with the old School of Tropical Medicine gives it a large basis and historical continuity, whilst on the other, it has an international status from the first, because it is built with American money for the benefit of the world at large, and not of Englishmen alone. London has many advantages as the site of such an institution, but its chief claim to outside assistance for public health work lies in this country's past record rather than its present needs. The Rockefeller Foundation's grant of £400,000 to build a new school is doubtless made in the lively expectation that this branch of English medicine is still capable of contributing something important and individual to the progress of mankind.

It will be remembered, however, that the grant was conditional on financial support from the British Government, and that the capital sum available was not to be used for running the School. Thus, from the time of its opening, the new building, though the gift of American citizens, will be a national concern, in which we hope to take a national pride. Moreover, thanks to the generous terms of the grant, the design and construction has been left to those who will control the fortunes of the School—notably, Dr. Andrew Balfou, (the Director) and the heads of the various divisions.

The type of building required needed long and careful consideration, and when preliminary plans had been prepared, a limited number of architects with experience in laboratory construction were invited to submit designs. The one prepared by Mr. P. Morley

FIG. 1.



The London School of Hygiene and Tropical Medicine.

Horder was approved, and has been executed by Mr. Verner O. Rees in association with him.

Having already published a full account[1] of the structure, we need now do no more than draw attention to some of its principal features. The accompanying photograph (Fig. 1) gives an idea of the outward appearance. The walls of Portland stone confer an air of permanence desirable in public buildings, and the work has been carried out with imagination as well as restraint. Thus the roving eye is at once edified by a frieze bearing the names of twenty-one pioneers of public health, and entertained by gilded insects on the balconies—surely the first official appearance of the louse as a decorative emblem?

The pioneers whose names are commemorated in the frieze are as follows:—

H. M. Biggs (1859–1925), Edwin Chadwick (1800–90), William Farr (1807–83), J. P. Frank (1745–1821), W. C. Gorgas (1854–1920), Edward Jenner (1749–1823), Robert Koch (1843–1910), C. L. A. Laveran (1845–1923), William Leishman (1865–1926), T. R. Lewis (1841–86), James Lind (1716–94), Joseph Lister (1827–1912), Patrick Manson (1844–1922), E. A. Parkes (1819–76), Louis Pasteur (1822–95), Max von Pettenkofer (1818–1901), John Pringle (1707–89), Walter Reed (1851–1902), Lemuel Shattuck (1793–1859), John Simon (1816–1904), and Thomas Sydenham (1624–89).

On the left of Fig. 1 is Gower-street, whilst on the right is the Keppel-street frontage and main entrance of the building. The block looking out on Keppel-street is mainly devoted to the rooms required for public use. The entrance hall affords direct access to a lecture theatre seating 250 persons. On the first floor is a library (Fig. 2), 33 feet wide and 120 feet long, apart from accessory rooms with which it communicates. On the third and fourth floors is the museum of hygiene, which has 15,000 square feet of floor space and will be open to the public. It is divided into three sections—namely, sanitary engineering, hygiene in

the general sense, and tropical medicine—and many of the exhibits will be furnished gratis by commercial firms and kept up to date by them.

The rest of the building takes the form of a letter H whose bases rest on the Keppel-street block, and the whole is thus built round two courtyards, measuring 160 × 80 and 100 × 80 feet, in such a way that light and air are amply supplied to every part. The various wings and floors are divided into the territories of the various divisions and departments of the School, according to the description we have already given, and there are numerous large laboratories and lecture rooms admirably reflecting the intention of the architect and Director to make "a workshop in which all the parts will be appropriate for their use, durable and lasting in construction, and in proportions exactly related to the whole." At first sight, this ideal and its achievement may seem far removed from the temple schools where medicine was first taught in Europe; yet the new building in Bloomsbury is nothing if not the modern concept of a temple to Hygeia. It is true that five-sixths of its space will be reserved for teaching in one form or another, and the post-graduate student will be asked to work rather than to pray. But these two functions are now regarded as largely interchangeable and the record of the staff is a guarantee that prayerful research after truth will not be lacking in the proper places and that the sacred animals of this particular temple will not be sacrificed in vain.

The organisation of the School, and its connexion with special institutions and branches of the public health service, have been made clear in a number of editorial articles in our columns, and a certain amount of information about them can be gained from the list of the principal members of the staff, which follows. There is, however, one aspect of the work to which special attention may be drawn. In the words of Prof. Jameson "it is earnestly desired that the School should become a centre to which all those interested in public health may look for assistance and advice. Members of the public health service will have a common-room placed at their disposal, and will be welcomed at all times—not only at the lectures given by the staff of the School, but also at the series of special afternoon lectures to be delivered by recognised experts on special public problems. We have no greater need at the present time," he says, "than for some sort of centre where our own public health workers can meet those from other lands, and discuss how best the experience of both may be made of service to the world at large. In this respect the London School of Hygiene and Tropical Medicine may be expected to play a not unimportant part."

The School was inaugurated as one of the constituents of the University of London in 1924, and the new building is intended to accommodate up to 250 students (of all nationalities), of whom probably not more than 100 will be working at tropical medicine. The present staff includes the following:—

Director—Dr. Andrew Balfour.

Directors of Divisions—Public Health: Prof. W. W. Jameson. Bacteriology and Immunology: Prof. W. W. C. Topley. Biochemistry and Chemistry: Prof. Harold Raistrick, D.Sc. Epidemiology and Vital Statistics: Prof. Major Greenwood, F.R.S. Tropical Medicine and Hygiene: Dr. Balfour. Medical Zoology: Prof. R. T. Leiper, F.R.S.

Directors of Departments—Chemistry: Prof. M. E. Delafield. Helminthology: Prof. Leiper. Protozoology: Dr. J. G. Thomson. Entomology: Dr. P. A. Buxton.

Director of Institute of Animal Parasitology—Prof. Leiper.

The Secretary of the School is Mr. R. W. Harris, the Curator of the Museum Dr. H. B. Newham, and the Director of Library Services, Dr. J. F. C. Haslam.

BRITISH INSTITUTE OF RADIOLOGY (incorporated with the Rontgen Society).—The following officers have been elected for the coming year:—President: Mr. C. Thurstan Holland, F.R.C.S.; Vice-Presidents: Sir W. H. Bragg, F.R.S., Dr. L. A. Rowden, and Dr. C. E. S. Phillips; Hon. Treasurer: Dr. D. B. McGrigor; Hon. Secretaries: Dr. Stanley Melville and Mr. G. Shearer, D.Sc.; Hon. Editors: Mr. G. W. C. Kaye, D.Sc., and Dr. R. J. Reynolds.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

LOCAL GOVERNMENT (SCOTLAND) ACT.

IN the House of Commons on Wednesday, July 10th, the debate was resumed on the motion that an Address be presented to His Majesty, thanking him for the Gracious Speech from the Throne.

Mr. MACPHERSON moved an amendment to the Address regretting that the Gracious Speech contained no reference to the demand for the suspension of the operation of the Local Government (Scotland) Act, 1929, until further inquiry had been made as to its effect, and consultation had taken place with the authorities concerned. He said that at the General Election there was scarcely a platform in Scotland on which the local government proposals of the late Government were not described by the Labour Party as anti-democratic, retrograde and reactionary, and instead of the miserable allocation of the new block grant which they were going to get under that Act, it was suggested that they were going to get huge schemes for Scotland as soon as the Socialist Party were in office. This amendment gave the Government an opportunity to respond to Scottish democratic opinion. The Secretary for Scotland could not deny that there was a very strong and clamant opinion in Scotland against the Act, and the real question was whether the Government were prepared to give an opportunity for consultation with the local authorities. The Royal and ancient burghs of Scotland had been the pioneers of liberty, and it was no wonder that they resented the treatment given them under this Act. They were being well-nigh obliterated, so far as real powers were concerned. The individuality of the *Royal burghs had been the saving* grace of local government in Scotland, but under this Act that individuality was to be destroyed, and they were to become the creatures and serfs of the mushroom-growth County Councils. The parish councils, the second body concerned, were a thoroughly democratic body and, as the Prime Minister had suggested in his excellent vote-catching speech in Glasgow, there was no reason whatever why because boards of guardians were being abolished in England the equivalent body in Scotland, the parish councils, should be abolished too. Education had always had a special significance in the minds of the people of Scotland, and there was great animosity against the late Government for trying to wipe away the 1918 Education Act.

The Prime Minister's Pledge.

Mr. RAMSAY MACDONALD, Prime Minister, said that he wished it were possible to suspend the operations of the Act and consult authoritative Scottish representatives as to amendments and then pass them as quickly as possible, but he did not know whether that was possible. If Labour had five years, not only of office, but of power, before the end of that time, a Labour Goverment would consider the whole broad question of Scottish administration. This Act had been passed and was in operation. Mr. Macpherson suggested that the Government should take from the Act all that it liked and suspend all that it did not like. Was it practical politics or commonsense to bring in a new Bill that was not a suspensory Bill, but a suspensory Bill with a thousand and one exceptions? It would be full of complexities and would take more time than the original Bill. The Government had found that with a little adjustment they could separate education and suspend the education provisions of the Act. A Bill had been drafted and it would be introduced and printed so that the House could see what it was, and find out if it would be possible to get it through in a reasonable time. If that could be done with goodwill, which did not *amount to agreement, and with a helpful* discussion, the Government would find the necessary time. The pledge which he gave at Glasgow held. What was in his mind was this: If they could save education they must give the other parts of the machine time to work, and after about twelve months of experience an inquiry would begin. That inquiry would be primarily into local administration though he would be very sorry if the larger question of Scottish self-government were excluded.

Sir JOHN GILMOUR (who was Secretary of State for Scotland in the late Government) said that one of the difficulties in dealing with education in Scotland had been that more and more the education of the children was being linked up with the health services of the country, and if they were to have even ad hoc education authority, separate from those authorities which had to deal with the health of the children, there must obviously be cases where there would be a lack of co-ördination, an increased and unnecessary expenditure, and a duplication of officials, which was *unnecessary and undesirable.* All he could say at this stage, speaking for the Conservative opposition, was that while, of course, they would consider any Bill which His Majesty's Government might introduce, they stood by the Act as it left that House. In their view the proper procedure, whatever the Government might do at a later stage, was to let the Act come into operation. It was not fair to the local authorities or to the House of Commons to rescind an Act of a previous Government in a manner which left great dubiety in the minds of those who had to administer these questions.

Mr. T. JOHNSTON, Under Secretary of State for Scotland, said that they were faced with this situation. The teachers' organisations in Scotland had definitely taken a stand, for reasons which they considered to be valid, against ad hoc authorities. On the other hand, practically the entire body of local administrators in Scotland, people of all sections and classes and political persuasions, had declared in favour of ad hoc authorities. The Prime Minister had suggested that the House would be well advised to accept not an amending Bill, not a repealing Bill, but a mere measure of suspension so far as the education clauses were concerned, and that forthwith there should be set up an *inquiry—whether a committee or a* commission he was not in a position to say—before which all sections of public opinion in Scotland could present their views, and the House of Commons at a very early date would then be in a position to give a considered judgment as to whether or not the ad hoc system should be retained. The Government would use all their persuasive powers to induce the local authorities, education and health, during the interregnum and the period of inquiry to prevent overlapping, and to see to it that the health of the children should be properly looked after.

Physically Defective Children.

The Duchess of ATHOLL said that in previous debates when the Act was passing through the House reference was made to the overlapping that had occurred in regard to clinics under the ad hoc system, and also to the economy that would be possible in the provision of hospitals under the Act in general. There was another respect in which coördination between the medical services of the schools and of other authorities seemed to her vital to the welfare of the children of Scotland. She referred to the question of defective children. Anyone who had studied the question of physically-defective children knew that in the last few years a new hope had arisen on the horizon for those children. They were told on the highest surgical authority that there was real hope in the great majority of cases of preventing lasting crippledom provided the children could get orthopædic treatment at an early enough age. In England and Wales fully half the education authorities had schemes for the orthopædic treatment of children, every one of which had been concerted jointly by the education committee of the Council and the maternity and child welfare authority. Such concerted action had been very much facilitated by the fact that in many areas, notably in the county burghs, both these authorities were part and parcel of the main authority—namely, the borough council. As a result of this concerted action, if they visited one of these hospital schools for orthopædic treatment, they found, if it had been in existence for some time, that the children in it were very young, almost in arms, or at any rate "toddlers," because the medical officers realised how much more valuable work could be done if the children were brought there long before school age. As a result of this treatment there was in some areas practical evidence of the decrease of crippledom. In Scotland they had so far very little orthopædic treatment for these children. They had a splendid educational system, but that was one of the ways in which there was room for improvement. It was just as vital in Scotland as in England that any treatment of that kind should include children below school age, as well as those who were old enough to attend school. Was it not obvious that they would have a far better chance of coördinated concerted action in cases of this kind if the education authority was the town or county council which in Scotland under this Act would also be the authority for maternity and child welfare? Take again the case of the mentally-defective children. There were many children of this type who were not receiving proper care either in Scotland or in England. There were those who were described as educable in regard to whom the responsibility fell on the education authority, while those who were regarded as non-educable were at present under the parish council and district board of control. Very often these children fell between two stools and nothing was done for them. She had heard of cases where parish officers had come to the medical officer of the school authority and implored him to declare educable children previously declared non-educable so that the parish council might be relieved of the responsibility of looking after these children. Lately in England and Wales these children had been the subject *of a long and exhaustive inquiry by a committee which* had recently reported. The main purport of that report has been to ask for much more flexibility in the way of treating these children, and many suggestions were made for much closer coöperation between the authorities for the educable and the non-educable. Did not all that show the importance of having machinery in Scotland under which education would be one department of the county council and the care of these unhappy children who were declared non-educable would be the responsibility of another branch of the same body? That would offer them a chance which had not yet been provided for them. She was very pleased to think that many medical men and women were included in the ranks of those newly returned to the House of Commons as representatives of the Labour party. She would ask them how they could find it in their hearts and consciences to vote for the repeal of provisions which gave so much greater opportunities for the care of mentally-defective children than they had ever yet been able to enjoy?

Mr. JAMES STEWART said that he was strongly in favour of the unification of the health services. He believed that if they unified those services under one authority they would promote efficiency in a most important direction. But the late Government in their Act *did not do that.* They merely transferred from one authority to another the carrying out of the administration of the work of the parish council and of education. It would be a good thing if the Government would press on with the inquiry so that they might help to bring about the reform in local government which everyone in that House without regard to party was agreed was necessary.

Major ELLIOT said let the House end this interminable grinding and regrinding of outworn problems and settle this problem here and now, and pass on to newer and fresher problems which urgently needed consideration. The Conservative party were against this inquiry proposed by the Prime Minister; they were against the Bill which he proposed to print and circulate, and would offer it the most definite and uncompromising resistance. They believed quite firmly that the proposals which they had brought forward were for the good of Scotland, and that four-fifths of them had commended themselves to the people of Scotland. It was not proposed to touch them; they were to be allowed to operate, although it was proposed to inquire into them. With regard to the ad hoc or ad omnia education authority opinion, medical opinion at any rate was agreed that the unification of the health services should take place; and many were agreed that the control of finance by the central financing body should take place. Take away the control of finance and take away the health services and what was left of this ad hoc authority which it was proposed to put under the authority of an ad omnia body? The decision had been made, and the inquiries had been held: let them at any rate try what could be done under the new system. The Conservative party would vote with the Government on this occasion; they had no hesitation in voting down the suggestion for suspending the whole of the Act; when the proposal to take out some of its provisions came forward they would meet it with the same uncompromising opposition.

Reply to the Debate.

Mr. WILLIAM ADAMSON, Secretary of State for Scotland, replying to the debate, said that as to the coördination of effort on health and relief services he saw no reason why that should not be secured by coöperation between the local authorities concerned as it had been in the past. In fact, the threat to the life of the education authorities should be a warning that such coöperation was vital if their independent existence was to be justified.

The amendment to the Address was negatived by 374 votes to 61.

The Functions of Education Authorities.

On Friday, July 12th, Mr. W. ADAMSON, Secretary of State for Scotland, presented a Bill to amend the provisions of the Local Government (Scotland) Act, 1929, with regard to the functions of education authorities.

The Bill was read a first time.

THE HOUSING SUBSIDY.

On Monday, July 15th, the House of Commons went into Committee, Mr. YOUNG in the chair, on the following resolution:—

> That it is expedient that the provisions of the Housing Acts (Revision of Contributions) Order, 1928, relating to houses subject to special conditions in the case of which contributions are to be provided under section two of the Housing (Financial Provisions) Act, 1924, should cease to have effect and that the same contributions should be payable and the same provisions applicable in the case of any such houses completed after the thirtieth day of September, nineteen hundred and twenty-nine, as are applicable in the case of any such houses completed on or before that date, and that all such additional amounts as

may become payable by virtue of this Resolution should be defrayed out of moneys provided by Parliament."

Mr. GREENWOOD, Minister of Health, in moving the resolution said, that he proposed, until September next year, when the next revision was due, to maintain the subsidy under the 1924 Act, at its present level. The same policy had been adopted in the case of Scotland. As regards the subsidy under the Chamberlain Act he proposed that that should be allowed to fall, as the late Government desired that it should fall. He had received an assurance from an important body representing the local authorities of this country, that if the subsidy order was modified as the Government were now proposing, he could rely on the local authorities continuing their building programmes without the hiatus which would otherwise inevitably follow. The resolutions, and the Bill which would follow, were designed merely to bring a measure of stability and continuity to the building of houses to let, while a larger and more comprehensive scheme was being prepared and being passed through Parliament. He hoped that with the hearty coöperation of the building industry, and in the closest association with the local authorities, to secure within a relatively short time, the adoption of a reinvigorated and more determined housing and slum clearance policy.

Mr. NEVILLE CHAMBERLAIN said, that nobody would grudge the expenditure of very much larger sums on housing if he were satisfied that they were being usefully employed, but in this case it was practically certain that the money would not benefit those who were crying for cheaper houses, but would merely be distributed in some way throughout the various branches of the building industry. The Government were entitled to put their ideas to the test of practice, and having made his protest he (Mr. Chamberlain) felt disposed to see whether hard experience would not bring the conviction which solid argument had failed at present to do.

Lieut.-Col. FREMANTLE said that hon. Members should think for a moment of the gigantic amount of money which was being spent upon subsidies and on housing. He would not object if they were getting their money's worth, but he was bound to say as a medical officer of health, that there were any number of practical health schemes being turned down because they would cost perhaps £1,000,000, £2,000,000 or £500,000. Yet the Government were now proposing to increase the housing subsidy to the extent of £6,000,000 a year. All medical officers recognised the gravity of the housing question, and that by improving the housing of the working classes they could do more than in any other way, with the exception of education, to prevent ill-health in future generations. But they must consider the cost.

Dr. MORGAN said they had just listened to a speech from one who belonged to the same profession as himself, and the Committee would excuse him if he said at the outset that they had in politics two opposite views in the medical profession—the one reactionary, and the other progressive.

Lieut.-Col. FREMANTLE: Which is which?

Dr. MORGAN said he had listened with great care to what Col. Fremantle had said, and he would excuse him if he said as another member of a profession in which they were accustomed to conciseness, definiteness, and order, that he was surprised at the vagueness, indefiniteness, and almost incoherency of what he had just said. The bulk of what Col. Fremantle had just said meant that the housing policy which was being proposed that day—a policy which was put into operation for a considerable time by the Government which Col. Fremantle supported—was an extravagant one. Col. Fremantle said that the expenditure on housing now proposed was wrong. The late Minister of Health had asked the question: "Is the subsidy always to go on?" The Labour Party's answer was: "Yes, as long as overcrowding goes on." The report of the Special Committee appointed by the National Housing and Town Planning Council, stated that the Glasgow slums were described in the annual report of the Scottish Board of Health for 1926. The Commission appointed to hold the local inquiry wrote, among other things, that it was impossible to draw any picture which could adequately describe the conditions under which they found human beings living in practically the whole of the houses which they inspected. There were, it was true, differences in degree, but all were hopelessly unfit for habitation . . . . . . Damp was present everywhere, the walls and ceilings in a large number of houses being literally soaking. Everywhere they noticed an almost total lack of sanitation, conveniences being few, and for the most part out of repair, and in some cases leaking down the stairs and even into the houses. . . . . A very revolting feature of the slums was that the majority of the houses were infested with bugs. . . . . . . The Labour Party knew of these conditions, and that was why they wanted money spent on housing. The policy of the Government was not extravagant. They wanted the Minister of Health to increase the subsidy still further, and to see that more houses were built.

The Resolution was agreed to.

HOUSE OF COMMONS.

THURSDAY, JULY 11TH.

Thefts of Dangerous Drugs.

Mr. GEORGE OLIVER asked the Home Secretary whether his attention had been drawn to the number of thefts of drugs from motor cars belonging to doctors; and whether, in view of the increasing number of this class of theft and the consequent dangers arising therefrom, he proposed to take any steps to prevent medical practitioners leaving dangerous drugs unattended or in other than some reasonably safe place.—Mr. CLYNES replied: Yes, Sir, there have been a certain number of such thefts, but I am informed by the police that they are satisfied that these thefts are ordinary cases of petty larceny, and have no connexion with any form of traffic in dangerous drugs. It is a little difficult to see what action I could usefully take in the matter, but it is desirable that medical practitioners and others who have these drugs in their possession should be particularly careful to avoid any risk of their being lost or stolen, and I hope the publicity which has been given to the matter will lead to greater care being taken.

Mr. OLIVER: Is the right hon. gentleman aware that 20 cases of this description have taken place during the last twelve months; that yesterday in Bolton, drugs of a similar character were stolen, and that it is stated in the press to be more than likely that a quantity sufficient to kill 20 people has found its way into the hands of children?

Mr. CLYNES: I am not aware of any occurrence of that kind, but I think that the publicity now given to the subject is likely to reduce the number.

Mr. OLIVER: Will the right hon. gentleman suggest to the medical profession that if cases of this kind increase or continue at the same rate, some method will have to be adopted of enforcing penalties; and is the right hon. gentleman aware that criminal negligence on the part of miners or railwaymen is invariably punished with imprisonment?

Mr. CLYNES: I can only add, that if the terms of my answer are not effective, further steps might be taken.

Education of Blind, Crippled, and Deaf Children.

Mr. FOOT asked the President of the Board of Education, the number of blind and crippled children in England and Wales for whom no educational provision was being made.—Sir CHARLES TREVELYAN replied: According to the returns furnished by Local Education Authorities there were, on Dec. 31st, 1928, 602 blind, and 5336 crippled children not attending any school, though it must not be inferred that in all these cases some provision has not been made for their education.

Mr. FOOT also asked for the number of deaf children of school age in England and Wales, and the number of these who were being taught in special schools or special classes for the deaf.—Sir CHARLES TREVELYAN replied: Returns furnished by local education authorities show that on Dec. 31st, 1928, there were 8935 totally deaf children of school age in England and Wales, and that of these 3464 were being taught in special schools.

FRIDAY, JULY 12TH.

Nursery Schools.

Mr. REGINALD YOUNG asked the President of the Board of Education, if he would, at an early date, give effective help for the establishment of nursery schools and regard these schools as an integral part of his educational policy.—Sir CHARLES TREVELYAN replied: I am anxious to see an expansion in the supply of nursery schools, and I am considering what steps I can most effectively take to encourage their provision.

Mr. KELLY asked for the number of nursery schools in Lancashire, and the number in England and Wales.—Sir CHARLES TREVELYAN replied: The number of nursery schools in Lancashire is four, and in England and Wales 28. In addition the Board have approved proposals for eight new nursery schools, one of which is in Lancashire, and proposals for at least five other schools, including two in Lancashire, are in contemplation.

Percentage Grants for Maternity and Child Welfare.

Mr. SIMON asked the Minister of Health, whether he was aware of the feeling among those interested in maternity and child-welfare work, that the provisions of the Local Government Act, 1929, will hamper the development of this work; and if he proposed to take the necessary steps to prevent this by restoring the percentage grant for these services.—Mr. GREENWOOD replied: I am aware that in certain quarters there is an apprehension of this kind, but I could not undertake at the present stage to introduce legislation for the continuance of percentage grants for maternity and child-welfare work. The effect of the new system of grants on the development of the public health services will be carefully watched.

Local Hospitals and the National Radium Fund.

Sir CHARLES CAYZER asked the Prime Minister if he would consider the desirability, in connexion with the National Radium Fund, of allowing local hospital authorities to send earmarked contributions to the fund so that these might be doubled by the State grant, as was the case in connexion with the Miners' Distress Relief Fund.—Mr. GREENWOOD replied: I am afraid that I cannot undertake to adopt the hon. Baronet's suggestion, since, as was stated in the House on April 16th, the contribution from public funds towards the purchase of further supplies of radium is subject to a maximum limit of £100,000, and the equivalent of this sum has already been raised by private subscription.

Sir C. CAYZER: In view of the fact that £100,000 has been or will be contributed to this fund by the general taxpayers, does not the right hon. gentleman think that provincial hospitals have a very strong claim to receive some assistance from the central fund?

Mr. GREENWOOD: That matter is now being dealt with, and a statement will shortly be made public as to the manner in which the radium supply is to be allocated.

Deaths from Small-pox and after Vaccination.

Mr. WELLOCK asked the Minister of Health the number of deaths that had occurred during the last twelve months from small-pox and from the after-effects of vaccination respectively.—Mr. GREENWOOD replied: During the twelve months ended May 31st last, 30 deaths occurred in which small-pox appeared in the coroner's certificate or the medical certificate as the cause or one of the causes of death. In the same period there were 20 deaths which were returned as having been associated with vaccination.

Hours Worked by Mental Hospital Attendants.

Viscount ELMLEY asked the Minister of Health the number of hours worked weekly by the attendants at the Thorpe Mental Hospital; and whether he had received any reports from his inspectors regarding this matter.—Mr. GREENWOOD replied: The weekly hours of duty amount to 60¼ hours actual working time spread over five days. The attendants, however, are allowed two whole days consecutively off duty each week, and also 21 days' leave each year. These arrangements are in accordance with the recommendations of the Joint Conciliation Committee of the Mental Hospitals Association and the National Asylum Workers' Union. The answer to the last part of the question is in the negative.

Slum Clearance Schemes.

Mr. ALPASS asked the Minister of Health, in view of the dimensions of the problem of slum clearance and the urgency of dealing with the same, if he would state what steps he proposed to take to carry out that part of the policy announced in the King's Speech.—Mr. GREENWOOD replied: It is the intention of the Government to introduce legislation on this subject at an early a date as practicable.

Liquor Advertisements in Post Offices.

Viscountess ASTOR asked the Chancellor of the Exchequer if he will state the revenue derived from advertising intoxicants in the post offices for each of the last two years; and whether he will consider abolishing this revenue in the national interest.—Mr. H. B. LEES-SMITH (Postmaster General) replied: The Government has decided that liquor advertisements should be excluded from post office buildings and publications as soon as the provisions of existing agreements permit. The revenue at present derived from these advertisements is about £4000 per annum.

Census and Overcrowding Standard.

Mr. GRAHAM-WHITE asked the Minister of Health if he would cause a new standard of overcrowding to be used in the Census Reports of the Registrar-General.—Mr. GREENWOOD replied: I propose to give consideration to this among other matters which will arise in connexion with the preparations for the next census.

MONDAY, JULY 15TH.

Vivisection of Dogs.

Sir ROBERT GOWER asked the Prime Minister whether he would grant facilities during the present Parliament for the consideration of a Bill to make the vivisection of dogs illegal.—Mr. RAMSAY MACDONALD replied: I cannot undertake to give special facilities for a Bill of the nature indicated by the hon. Member. Private Members interested will no doubt use, as before, the facilities they have for testing the opinion of the House on the subject.

Education of Defective Children.

Dr. MORGAN asked the President of the Board of Education the comparative cost of educating a normal child, a blind child, a deaf child, and a mentally defective child, respectively; and whether part of this cost could be saved in future years by a judicious health expenditure in infant years by the development and extension of infant welfare centres.—Sir CHARLES TREVELYAN replied: The cost per child in an ordinary elementary school in 1927–28 was £11 15s. 4*d*. According to the latest statistics available, the cost (excluding loan charges) of educating a blind child is approximately £29 in a day school and £88 in a residential school, the corresponding figures for the deaf being £48 and £82, and for the mentally defective £25 and £71. The second part of the hon. Member's question raises issues which it is difficult to deal with in the limits of an answer to a question.

Mentally Deficient Children.

Dr. MORGAN asked the President of the Board of Education the total number of mentally deficient children in Great Britain now receiving education in special schools; whether he was considering further developments of such institutions in the near future; and whether the teachers were required to have special qualifications.—Sir CHARLES TREVELYAN replied: The number of mentally deficient children attending certified special schools in England and Wales for the year ending Dec. 31st, 1928, was 15,339. As regards the second part of the question, the hon. Member will be aware that a Joint Committee of the Board of Education and the Board of Control have recently presented a report which is receiving my careful consideration. I am sending the hon. Member a copy of a memorandum indicating the requirements in regard to teachers in schools for mentally defective children.

Lunacy Law Reform.

Mr. HORE-BELISHA asked the Home Secretary whether it was the intention of the Government to put into operation the recommendations of the recent Royal Commission regarding the reform of the existing lunacy law.—Miss LAWRENCE replied: This matter is under consideration, but my right hon. friend is not at present in a position to indicate when it will be practicable to introduce legislation on the subject.

Experiments on Animals.

Mr. BROMLEY asked the Home Secretary whether applicants for licences or certificates, under the Cruelty to Animals Act of 1876, for the performance of experiments on animals were required to state the number of animals they proposed to use for such experiments; whether the Home Office had any record as to the number of animals used, as distinct from the number of experiments performed, under that Act in 1927; and whether the Home Office had any record of the number of dogs and the number of cats used for experiments in 1927, under Certificate B, plus EE.—Mr. SHORT (Under Secretary to the Home Office) replied: The answer to each part of the question is in the negative. With regard to the last part, I may point out that Section 5 of the Act, which governs Certificate EE, does not distinguish between cats and dogs.

TUESDAY, JULY 16TH.

Operative Treatment of Physically Defective Children.

Duchess of ATHOLL asked the Secretary for Scotland the number of education authorities having approved schemes for the orthopædic treatment of physically defective children that included operative treatment where necessary and remedial after-care; and the number of such schemes that were provided jointly with the authorities for maternity and child welfare.—Mr. ADAMSON replied: No education authority makes independent provision for major operative treatment of physically defective children, such treatment being ordinarily carried out by the voluntary hospitals. Thirteen education authorities have approved arrangements for the treatment of deformities by massage and remedial exercises, and twenty-one education authorities have approved arrangements for treatment by orthopædic appliances. In practice all education authorities supply splints, surgical boots, and such like appliances where necessary. As regards the last part of the question, there is no scheme for orthopædic treatment provided jointly by an education authority and a maternity service and child welfare authority, though there are a number of cases in which there is coöperation between the two authorities in the use of premises.

Government and Local Government Act.

Mr. SCURR asked the Minister of Health, whether he had received representations from many important public bodies asking for the postponement of the coming into force of the Local Government Act; and, if so, whether he could make any statement on the matter.—Miss SUSAN LAWRENCE, Parliamentary Secretary to the Ministry of Health, replied: My right hon. friend has received a certain number of representations from local authorities; it is not the intention of the Government to postpone the coming into force of the Act.

Town Planning in Built-up Areas.

Mr. SCURR asked the Minister of Health whether it was his intention to introduce legislation applying the principle of town planning to built-up areas.—Miss LAWRENCE replied: My right hon. friend hopes to introduce legislation on the subject.

Highlands and Islands Medical Fund.

Sir ROBERT HAMILTON asked the Secretary for Scotland whether he could state the present condition of the Highlands and Islands (Medical Services) Fund; whether the beneficial services assisted by the fund were being in any way curtailed; and whether steps were being taken to maintain the fund on a sound financial basis.—Mr. ADAMSON replied: The war-time accumulations in the fund will be exhausted within the next few months, and the present statutory income of the fund will require to be supplemented in order that the current year's liabilities may be met. While there has been no curtailment of established services assisted from the fund, and certain expansions have been sanctioned from year to year, other desirable developments have been delayed pending reconstitution of the fund. I have the whole position under consideration, and hope to be able to submit proposals to the House on an early date.

Ophthalmic Clinics.

Mr. DAY asked the Minister of Health whether he would give particulars of any experimental or ophthalmic clinics that had been set up under the provisions of the National Health Insurance Acts during the last six months.—Mr. GREENWOOD replied: No regulations have yet been made under the National Health Insurance Acts governing the provision of ophthalmic and other forms of treatment of insured persons in clinics, and, consequently, no clinics have up to the present time been set up under the provisions of the Act. A certain number of dental and ophthalmic clinics have been set up by private enterprise, and some insured persons have elected to obtain through them treatment towards the cost of which their approved societies have contributed by way of additional benefit; but no official recognition has yet been given to any of such clinics, and their continued use as agencies for the provision of treatment to insured persons entitled to additional benefits will be conditional upon their complying with such requirements as may, in due course, be laid down by regulations under the Act.

Obituary.

HAROLD ANDREW KIDD, C.B.E., M.R.C.S. ENG.

Dr. H. A. Kidd, who died suddenly at his home in London on July 12th, was the first medical superintendent of the West Sussex Mental Hospital, better known as Graylingwell, near Chichester, and held this post for 30 years. When the hospital was opened in 1896, Dr. Kidd took personal charge not only of the clinical side, but of the organisation as a whole, and worked out the details of administration with such success that for many years Graylingwell was famous as one of the most efficiently run mental hospitals in the country. During the war, Graylingwell was converted into a military hospital, and Dr. Kidd was appointed officer commanding, with the rank of Lieut.-Colonel, R.A.M.C. The patients in residence were removed to other mental hospitals, and nearly 30,000 wounded or sick soldiers were treated at Graylingwell. Operating theatres were devised, wards were converted, apparatus was procured, and Dr. Kidd had all the responsibility connected with this great change, and afterwards the arduous task of re-conversion. He was given a C.B.E. for his services, and received praise from all who inspected the ingenious temporary arrangements.

Dr. Kidd received his medical education at St. Mary's Hospital, which he entered with a science scholarship in 1883, qualifying in 1889. He turned at once to psychiatry, taking the post of assistant medical officer at the London County Asylum at Cane Hill, which he held for seven years. As a student, and indeed throughout his life, he was a keen athlete, playing Rugby football in his youth and later cricket, tennis and golf, with more than average skill. For years a team from St. Mary's Hospital went to Chichester for an annual cricket festival organised at Graylingwell and Dr. Kidd loved to welcome past and present students of the hospital to his delightful home. Dr. Kidd was a keen freemason and was Master of the Sancta Maria lodge in 1914, coming up to London regularly for its meetings. In this way he renewed old friendships and his connexion with St. Mary's was further strengthened in recent years by the entry of his eldest son, who qualified from the hospital in 1927.

Dr. Kidd was a genial and charming host and he delighted to show visitors ignorant of the routine of a large mental hospital how much liberty was compatible with the necessary discipline. He was keen to welcome any suggestions for improving conditions and was convinced that the difficulties standing in the way of further progress were mainly economic. His constant aim was to cut down only such administrative expenses as did not contribute to the comfort of patients or staff and to make Graylingwell as far as possible a self-supporting colony with a strong team spirit. He was rewarded by the trust reposed in him by his committee and the affection with which he was regarded alike by patients, colleagues, and nursing staff throughout his career.

Medical News.

UNIVERSITY OF OXFORD.—The Radcliffe Scholarship in Pharmacology has been awarded to J. R. Braybrooks, New College, and G. S. Grist, Pembroke College, who are equal in merit.

UNIVERSITY OF LONDON: *University College.*—The following awards have been made in the Faculty of Medical Sciences:—

Entrance Scholarship: J. C. Thomas (Christ's Hospital, Horsham).

Bayliss-Starling Memorial Scholarship in Physiology: F. G Young.

Cluff Memorial Prize (Anatomy, Physiology, Pharmacology, and Chemistry): E. A. Devenish.

UNIVERSITY OF SHEFFIELD.—At recent examinations the following candidates were successful:—

M.D.—Janet Breakey.

FINAL EXAMINATION FOR M.B., CH.B., WITH HONOURS.

Class II.—Frank Ellis and T. H. Pullar.

FINAL EXAMINATION FOR M.B., CH.B.

W. H. Carlisle, Iris M. Moody, and Isaac Slesnick.

UNIVERSITY OF LIVERPOOL.—Dr. W. J. Dilling has been appointed Dean of the Faculty of Medicine, and Prof. W. H. Gilmour Secretary of the Dental Board of Studies.

SOCIETY OF APOTHECARIES OF LONDON.—At recent examinations for the Society's diploma of Master of Midwifery the following candidates were successful: B. P. Baliga, F.R.F.P.S. Glasg., C. A. Birch, M.D. Liverp., and W. C. V. Brothwood, M.B. Manch.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—A quarterly meeting of the Council was held on July 11th, with Lord Moynihan, the President, in the chair. The President announced the re-election to the Council of Sir Holburt Waring, Mr. C. H. Fagge, and Mr. W. Sampson Handley, and the election of Prof. Graham Simpson. The newly elected members were introduced and took their seats in the Council.

Lord Moynihan was re-elected President, and Mr. C. H. Fagge and Mr. V. Warren Low were elected Vice-Presidents for the ensuing collegiate year.

Mr. R. H. Burne, F.R.S. (Physiological Curator), Mr. C. F. Beadles (Pathological Curator), Sir Frank Colyer (Honorary Curator of the Odontological Collection), and Mr. C. J. S. Thompson (Honorary Curator of the Historical Section of the Museum) were re-elected to their respective posts. Mr. W. R. Le Fanu, Second Librarian to the Hellenic Society, was appointed Assistant Librarian to the College.

Mr. H. J. Burrows was appointed Beaverbrook Research Scholar of the College for 1930 and 1931. Until the end of this year he will pursue tissue culture research at the Research Hospital, Cambridge. The Hallett Prize was awarded to Mr. L. A. Riddell, M.B. New Zealand, for the recent examination in Anatomy and Physiology for the Fellowship.

The Council elected the following Professors and Lecturers for the ensuing year:—

Hunterian Professors.—Sir John Rose Bradford, P.R.C.P., Mr. Victor Bonney, Mr. J. H. Fisher, Mr. G. E. Gask, Mr. W. Sampson Handley, Sir Arthur Keith (six lectures) and Mr. Geoffrey Keynes.

Arris and Gale Lecturers.—Mr. W. McAdam Eccles, Mr. E. R. Flint, Mr. R. H. O. B. Robinson.

Erasmus Wilson Lecturers.—Mr. C. E. Shattock and Mr. C. P. G. Wakeley.

Arnott Demonstrator.—Sir Arthur Keith.

Dr. John Eyre, bacteriologist at Guy's Hospital, was appointed Examiner for Part I. of the Examination for the Diploma in Public Health.—Lord Moynihan presented to the College a portrait-group of the Council in 1927–28, painted by Mr. Moussa Ayoub.—It was decided to have printed Plarr's "Lives of the Fellows," which have been edited by Sir D'Arcy Power, with the assistance of Mr. W. G. Spencer and Prof. G. E. Gask; and a guide to the Historical Section of the Museum prepared by Mr. C. J. S. Thompson.

The Fellowship of the College was conferred on R. L. Almond, and the Membership on V. L. Misso and R. M. Sargent, who had passed the necessary examinations and complied with the regulations.

Licences in Dental Surgery were granted to the following:

N. L. Barber, S. W. Beales, R. G. Boodle, D. S. Clogg, Marcus Cohen, F. N. Corfe, F. L. Crameri, J. P. Davies, W. F. Goddard, W. B. Harris, H. T. Honeybourne, G. E. S. Jeffery, S. R. Johns, R. E. L. Jones, F. F. Kennedy, J. J. D. King, J. F. Lockwood, A. A. Mallet, R. H. Matthews, J. I. Mathias, C. E. B. Maytum, David Monk, C. G. Moore, R. O. Murray, A. B. Nielsen, C. A. Pank, D. L. Parkes, William Peebles, H. E. Pickering, J. E. D. Pollard, T. W. E. Pugh, J. C. Read, L. G. Rowe, L. A. Sewell, P. R. Shepherd, Samuel Sidebotham, H. F. Strickland, W. L. Sutcliffe, C. A. Tinn, and A. L. Wraight.

The following diplomas were granted jointly with the Royal College of Physicians of London:—

Diploma in Psychological Medicine.—Leonard Barber, Flora H. MacD. Calder, Viola C. Cameron, Ruby T. Curr, S. W. Davies, J. H. Ewen, E. A. Haslam-Fox, J. E. S. Lloyd, S. V. S. Rao, and Kathleen M. Todd.

Diploma in Laryngology and Otology.—B. R. Chaudhri, Patrick Hickey, G. J. Hutchison, Rajnarain Kacker, W. A. Kerr, K. S. May, R. F. Paterson, C. L. Rosenfield, and Gobind Vaishnavi.

ST. THOMAS'S HOSPITAL.—An address and a sum of money from past and present students will be presented to Robert Hopkins, Bedell of the Medical School of St. Thomas's Hospital, at the annual dinner on Oct. 4th, to celebrate his fiftieth year in the service of the School.

BEIT MEMORIAL FELLOWSHIP FOR SCIENTIFIC AND MEDICAL RESEARCH.—At the last meeting of the Trustees of this establishment the report of the hon. sec., Sir J. Kingston Fowler, alluded to the frequent resignation of the Fellowship as a practical tribute to the status of those who were selected for them, inasmuch as it meant the appointment of the Fellows to permanent posts.

The following were elected to Fourth Year Fellowships:—Richard J. Lythgoe (Electric reactions in connexion with Special nerves) and Maurice W. Goldblatt (carbohydrate metabolism).

The following elections have been made to Junior Fellowships, the subjects of research being announced:—

Robert Hill (from the Biochemical laboratory, Cambridge), specificity of hæmoglobins.

Ann Bishop (from the Molteno Institute for Parasitology, Cambridge), completion of studies on the morphology and development of Trichomonas of man and monkeys in culture.

Cuthbert Leslie Cope (from the Radcliffe Infirmary and Physiological and Biochemical Laboratories, Oxford), the diuretic responses of normal and pathological kidneys in man to tubule diuretics, especially to intravenous sodium sulphate.

Leonard Ernest Bayliss (from the department of Physiology and Biochemistry, University College, London), the metabolism of the isolated heart and kidney by means of the heart-lung and heart-lung-kidney preparation and the artificial oxygenator of Bayliss, Fee, and Ogden.

Walter Phillips Kennedy (from the Physiology Department and Royal Infirmary, Edinburgh), investigations into the function of the Ovary, including *in vivo* and *in vitro* actions of oestrin and the hormone of corpus luteum. The research is now in progress.

Eric Boyland (from the Lister Institute), investigation of the mechanism of carbohydrate metabolism.

Edwin Martin Case (from the Sir William Dunn Institute of Biochemistry, Cambridge), the study of the metabolism and thermodynamics of muscle. This research is already in progress.

Kenneth A. C. Elliott (from the Biochemical Laboratory, Cambridge), the study of biological oxidations.

Margaret Honora Roscoe (from the Lister Institute), continuation of the investigation begun in conjunction with Dr. Aykroyd (Aykroyd, 1929) on the distribution of the anti-pellagra vitamin B2 in natural foodstuffs and a comparison with the distribution of the anti neuritic vitamin B1. The methods of vitamin assay will be those described by Chick and Roscoe (1928, 1929) using the growth of rats as criterion. The distribution of the antineuritic vitamin has hitherto only been studied in connexion with the prevention and cure of polyneuritis in birds. 2. Investigation of possible synthesis of vitamin B1 and B2 in the intestine, as the explanation of the phenomenon of refection described by Fridericia of Copenhagen (1926) and Roscoe (1928). Study of the anti-pellagra vitamin B2 in connexion with the antineuritic vitamin B1.

Medical Diary.

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

MONDAY, July 22nd.—2.30 to 5 P.M.: Medical, Surgical and Gynæcological Clinics. Operations.

TUESDAY.—2.30 to 5 P.M.: Medical, Surgical, Ear, Nose and Throat Clinics. Operations.

WEDNESDAY.—2.30 to 5 P.M.: Medical, Skin, and Eye Clinics. Operations.

THURSDAY.—11.30 A.M.: Dental Clinics. 2.30 to 5 P.M.: Medical, Surgical, Nose, Throat, and Ear Clinics. Operations.

FRIDAY.—10.30 A.M.: Throat, Nose and Ear Clinics. 2.30 to 5 P.M.: Surgical, Medical, and Children's Diseases Clinics. Operations.

ST. PAUL'S HOSPITAL, Endell-street, W.C.

THURSDAY, July 25th.—4.30 P.M., Mr. Kenneth Walker: The Enlarged Prostate.

Appointments.

BAKER, Doris, M.D., M.R.C.P.Lond., has been appointed Assistant Physician to the South London Hospital for Women, Clapham Common.

COTTRELL, J., M.B., Ch.B. Edin., Certifying Surgeon under the Factory and Workshop Acts for Grimsby.

GAVIN, F. W., M.D., Ch.B. Edin., D.P.H., Asst. M.O.H. and School M.O. for Croydon.

St. Thomas's Hospital: COOKE, A. M., B.M., B.Ch. Oxf., M.R.C.P.Lond., Deputy Director of the Medical Unit; CHESMAN, W. E., M.B., B.Chir.Camb., M.R.C.P.Lond., First Assistant to the Medical Unit; JONES, B. H., M.D., B.S. Lond, M.R.C.P.Lond., Resident Assistant Physician.

ILFORD, Borough of: EDGECOMBE, K., M.D., Ch.B., D.P.H. Liverp., Assistant Medical Officer of Health; and CROW, A. F., M.B., Ch.B., L.D.S., Assistant Dental Surgeon.

Vacancies.

For further information refer to the advertisement columns.

Ashton-under-Lyne District Infirmary.—Asst. Radiologist. £300.

Barnsley, Beckett Hospital and Dispensary.—Jun. H.S. £140.

Birkenhead General Hospital.—Cas. S. £100.

Birmingham City Mental Deficiency Institution, Coleshill Hall.—Med. Supt. £700.

Birmingham, General Hospital.—Res. H.P £70. Also Second Asst. Visiting Anæsthetist. £50.

Birmingham University.—Lecturer in Physiological Dept. £400.

Birmingham Union, Erdington House.—Res. Asst. M.O. £250–£350.

Bootle Borough Hospital, Derby-road.—Sen. M.O. Also Two Jun. M.O.'s. At rate of £150 and £125 respectively.

Birmingham and Midland Eye Hospital, Church-street.—Res. Surg. O. Also Two H.S.'s. £160 and £110 respectively.

Bradford Children's Hospital.—H.S. Also H.P. Each £120.

Bradford Royal Infirmary.—Two H.S.'s. Each £150.

Bristol General Hospital.—H.P.'s and H.S.'s. Also Obstetric Officer. Each at rate of £80. Also Cas. H.S. At rate of £30.

British Red Cross Society's Clinic for Treatment of Rheumatic Diseases, Park Square East, Regent's Park.—Med. Supt. £600.

Burton-on-Trent General Infirmary.—2nd Res. H.S. £150.

Buxton, Devonshire Hospital.—Asst. H.P. At rate of £150.

Cairo, Egyptian University.—Prof. of Clinical Pathology. £E.1500.

Chester Royal Infirmary.—H.S. and Cas. O. £120.

Coventry and Warwickshire Hospital.—Res. H.S. £125.

Croydon Mental Hospital, Upper Warlingham.—Second Asst. M.O. £350.

Derby, Derbyshire Hospital for Women.—Hon. Asst. S. Also H.S. At rate of £150.

Devonport, Royal Albert Hospital, &c.—Asst. H.S.'s. At rate of £50.

Dewsbury and District General Infirmary.—H.S. £200.

Doncaster Royal Infirmary.—H.S. £150.

Dudley, Guest Hospital and Eye Infirmary.—H.S. £150–£175.

Dundee Royal Infirmary.—Visiting M.O.

Durham County and Sunderland Eye Infirmary.—Locum.

East Ham Memorial Hospital, Shrewsbury-road, E.—Res. M.O. At rate of £150.

Evelina Hospital for Children, Southwark, S.E.—H.S. At rate of £120.

Exeter, Royal Devon and Exeter Hospital.—Asst. H.S. At rate of £100.

Exminster, Devon Mental Hospital.—Jun. Asst. M.O. £300.

Gloucester, Gloucestershire Royal Infirmary, &c.—Second H.S. At rate of £100.

Great Yarmouth General Hospital.—Jun. H.S. £100. Also Sen. H.S. £150.

Hull and Sculcoates Dispensary.—M.O. £500.

Hull Royal Infirmary.—Cas. H.S. At rate of £130.

Indian Medical Service.—Commissions.

Liverpool, St. Paul's Eye Hospital, Oldhall-street.—H.S. £60.

London Temperance Hospital, Hampstead-road, N.W.—Cas. O. At rate of £120.

Longton Hospital, Stoke-on-Trent.—H.S. £120.

Lowestoft and North Suffolk Hospital.—H.S. £120.

Macclesfield General Infirmary.—Res. H.S. £180.

Manchester City.—Asst. Tuberculosis Officer. £650.

Manchester, Royal Eye Hospital.—Jun. H.S. £120.

Miller General Hospital, Greenwich-road, S.E.—Hon. P. to Skin Dept.

Nottingham City Education Committee.—Sen. Asst. School M.O. £600.

Philadelphia, Hospital of the Woman's Medical College.—Hospital Resident.

Plymouth, City and Port of.—Asst. M.O.H. £600.

Plymouth Poor-law Institution.—Res. Locum Tenens.

Plymouth, Udal Torre Sanatorium, Yelverton.—Res. M.O. £450.

Prince of Wales's General Hospital, Tottenham, N.—Hon. Asst. P.

Queen Mary's Hospital for the East End.—Hon. Asst. Radiologist.

Radcliffe-on-Trent, Notts County Mental Hospital.—Sen. Asst. M.O., &c. £520.

Rotherham Hospital.—Sen. H.S. £200.

Royal Army Medical Corps.—25 Commissions.

St. Mary's Hospital for Women and Children, Plaistow, E.—Res. and Asst. Res. M.O.'s. At rate of £175 and £120 respectively.

Salisbury Municipality, S. Rhodesia.—M.O.H. £900.

Sheffield Royal Infirmary.—Surg. Reg. £200. Also Asst. Cas. O. H.S., Ophth. H.S., and Asst. Ophth. H.S. Each at rate of £80.

Society of Apothecaries of London, Water-lane, Queen Victoria-street, E.C.—Examiner in Midwifery.

Southampton, Royal South Hants and Southampton Hospital.—Cas. O. At rate of £120.

Stafford, Staffordshire General Infirmary.—H.S. At rate of £200.

Stockport Infirmary.—H.S. £175.

Swansea Hospital.—Cas. O. £150.

West London Hospital, Hammersmith, W.—Res. Anæs. At rate of £100.

West Riding C.C., Yorkshire.—Temporary Pathologist. £750.

Willesden General Hospital, N.W.—Two Clin. Assts. to Special Departments. Also Ophthalmic Surgeon.

Winchester, Royal Hampshire County Hospital.—Res. H.S. £150.

Worcester County and City Mental Hospital, Powick.—Jun. Asst. M.O. £350.

Worthing Hospital.—H.S. At rate of £150.

The Chief Inspector of Factories announces the following vacant appointments for Certifying Factory Surgeons: Addingham (York, W.R.), Uffculm (Devon), Haverhill (Suffolk), and Clwt-y-bont (Cærnarvonshire).

Births, Marriages, and Deaths.

BIRTHS.

CALVERT.—On July 12th, 1929, to Nancy (*nee* Marsden), wife of Dr. E. G. B. Calvert, 132, Harley-street, W.—a son.

DUCHESNE.—On July 10th, at "Langton," Swanage, Dorset, the wife of H. W. Duchesne, L.D.S., R.C.S.Eng., of a son.

MARRIAGES.

MARTEN—MONTEITH.—On July 6th, at Christ Church, Westminster, Robert Humphrey Marten, M.D., of Adelaide, South Australia, and Artillery Mansions, S.W., to Mary Elizabeth, elder daughter of the late Charles Dickey Monteith and Mrs. Monteith, of Carlton-hill, Exmouth.

REEVES—ENGLISH.—On July 13th, at St. Matthew's, Westminster, Guy Kingham Reeves, L.R.C.P.Lond., M.R.C.S. Eng., of Tulse-hill, S.W., to Audrey Malcolm English, of Poynders-road, S.W.

RUSSELL—WATERS.—On July 10th, at St. Mary Magdalene's Church, Westerfield, Henry Stewart Russell, B.Sc., M.B., Ch.B., to Betty Coyne Waters, B.A.Cantab., M.B., B.S., elder daughter of Mr. and Mrs. H. E. Waters, Westerfield, Suffolk.

DEATHS.

BISHOP.—At Bathurst, Gambia, West Africa on 20th May, 1929, Thomas Bishop, L.R.C.P.E., &c., J.P. and Coroner, aged 61.

BURY KNIGHT.—On July 10th, at Wooldown, Marhamchurch, Bude, Henry Bury Knight, M.R.C.S., L.R.C.P., aged 58.

CROOK.—On July 11th at Dumpton Cottage, Park-avenue, Broadstairs, Herbert Evelyn Crook, M.D.Lond., F.R.C.S. Eng., Barrister-at-Law of the Middle Temple, aged 64.

IRVING.—On July 12th, at Bedford, Major Henry Court Irving, L.R.C.P., L.R.C.S., late of British Guiana Medical Service, aged 68 years.

KIDD.—On July 11th, suddenly, at Addison Court-gardens W., Harold Andrew Kidd, C.B.E., late Medical Superintendent, Graylingwell Mental Hospital, Chichester, and late Lieut.-Col. R.A.M.C., aged 65.

MALING.—On Tuesday, July 9th, at St. Monica's, Micheldever-road, Lee, George Alan Maling, V.C., M.A., M.B., B.Ch. Oxon., aged 40 years. Interment at Chislehurst Cemetery.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Comments, and Abstracts.

FOUR MILLENIUMS OF CHINESE MEDICINE.

BY K. C. WONG.

To the uninformed the term Chinese medicine conveys either a dark picture of charms, incantations, and magic, or one of disgusting concoctions, painful manipulations, unsightly plasters, and worthless remedies. Everywhere, however, superstition and healing are so closely related that it may be impossible to draw a line between them, and while there are quacks in China just as in other countries, the Chinese regular practitioner treats diseases according to rules and standards and has a clear conception of the responsibilities of his calling. From a mass of folly and nonsense there has been produced a rational, semi-scientific, and dignified empirical practice, which is based upon the accumulated knowledge of 40 centuries and which represents the thoughts and experiences of many bright minds. Chinese medicine as it exists at the present time is comparable to the situation of medicine in Europe during the sixteenth century, and viewed from the historical standpoint, it was at least equal to, if not more profound than, that of other countries at the same period. It certainly merits deeper investigation than it has heretofore received, when it will earn greater appreciation. Many books and very many articles have been written on the superstitions of Chinese medicine, but its more scientific aspects have scarcely been touched upon. The present short sketch attempts to deal more particularly with its proper position in history, its value and defects, and its relation to scientific medicine. In this brief survey no attempt will be made to give full references for the conclusions arrived at; only the outline of the medical conception of the various dynasties will be drawn.

FOUR EPOCHS.

Four distinct epochs may be distinguished: (I.) From the dawn of history to the end of the Shang Dynasty, 1154 B.C., may be termed the legendary period. Thereafter the accounts were more authentic and the legendary developed into the historical. (II.) Beginning with the Chow and ending with the Tang Dynasty (1000 B.C. to A.D. 960) may be styled the historical or classical period. Chang Chung-king, the Hippocrates of China, and Hua To, the most celebrated surgeon, lived late in the middle of this period—viz., A.D. 195. (III.) From the eleventh to the seventeenth century there was a marked change in Chinese medical thought. Instead of the pedantic worship of the ancients the publications of this period are mostly controversial in character, old writings being attacked as well as current opinion. Four schools were recognised and subsequent writers all revolved round these different schools. This period may be called the mediæval or controversial period. (IV.) With the introduction of Western medicine in A.D. 1805 came the modern or transitional period. The most prominent feature of this period is the struggle for supremacy between the old and the new. The latter, however, is slowly and steadily gaining ground. Though it may take some time the dawn of another golden era is looming large on the medical horizon of China.

I. THE ANCIENT OR LEGENDARY PERIOD.

There are many legends concerning the founders of Chinese medicine. The first was Sheng Nung, 2737 B.C., the originator of the Materia Medica. Like Mithridates, King of Pontus, who achieved a reputation in the art of taking poisons, he has said to have tasted 70 different kinds of poison every day and established the art of pharmacology. To him is usually ascribed the writing of the Pentasso or great Herbal which is supposed to be the earliest Chinese scientific work. Sheng Nung is venerated as the Father of Medicine. Another noted and nearly contemporary figure in Chinese healing art was Prince Hwang Ti, 2697 B.C. In conjunction with Chi Pok, one of his Ministers, he was said to have written the famous Nei Ching or Canon of Medicine. But historical researches prove that this important medical classic was not composed by him but was a later production written probably about 1000 B.C. What the Four Books are to the Confucianists the Nei Ching is to the native doctors. Upon it is built most of the indigenous medical literature of China, and so important is it considered by medical men that even at the present time, 3000 years after it was written, that it is still regarded as the greatest authority, though it is the oldest Chinese treatise on medicine proper extant. It has been translated into

French by Dabry. A third name to be mentioned in this legendary period is I Yin, the able and faithful Prime Minister of Emperor Tang, founder of the Shang Dynasty, 1783 B.C. He is credited with the discovery of making medicinal decoctions.

As with the early civilisations of other countries religion and astrology merged into healing, so in China the medical profession was from the earliest times under the sway of priestcraft and sorcery, and it was not until the Chow Dynasty, 1140 B.C., that the functions of these two professions were separated. An interesting sidelight on this situation is thrown by the formation and development of the ancient written character for doctor. It is composed of three parts; at the top and left corner is a quiver, at the right corner a spear, and below is the symbol common to sorcerer or priest. The significance is that the priest employs strong weapons to kill or expel the demons of disease. Later this last symbol was changed to that for wine, signifying that the profession was no longer in the hands of the priests but had passed to the regular doctors who administered wines (elixirs) to their patients. A study of the archaic writing of Chinese characters will throw much light on the medical conditions of the various periods.

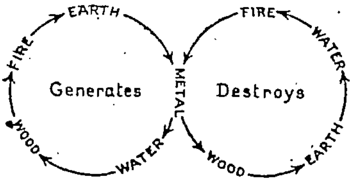
II. THE HISTORICAL OR CLASSICAL PERIOD.

Documented history does not extend further back than the middle of the Chow Dynasty, 723 B.C., one of the most glorious periods in Chinese history. Literature, art, philosophy, government, religion, and all that is included in the term civilisation flourished and reached a high degree of development. Laotzu, Confucius, Mencius, and most of the famous philosophers lived during this period, and these men speculated on all things, and their influence was so great that it was felt in every branch of literature. But, as a result, we find medicine no longer an effective practical although restricted art based upon observation and knowledge. We see rather, masquerading under its name, pretentious systems of healing carried to an absurdly extravagant pitch; we have elaborate systems of theoretical knowledge developing in complexity without gaining in meaning, tending to become less and less effective in practice. The study of medicine was dominated by the scholastic subtleties of visionary philosophers, and reverence for authority became petrified formalism with a pedantic excess of detail. And these varied speculations on the nature and causation of disease led to the evolution of two doctrines which formed the basis of the whole of Chinese medicine.

Yang and Yin.

The first doctrine is that of the two principles or primordial elements called "Yang" and "Yin." Everything under the sun is supposed to originate from them. They are generally represented by a circle named the great absolute or infinite void, which is divided into two pear-shaped bodies by a curved line. Attendant upon these diagrammatic elements are eight symbols, each made up of a combination of triple lines whole and broken, arranged in such a manner as not to repeat itself. This Pah-kwa or eight trigrams is supposed to date from Fuh Hsi, 2353 B.C.—the plan being revealed to him on the back of a supernatural animal called a dragon horse, that rose from the waters of the Yellow River. Each of the eight trigrams has a special name with symbolic and fanciful meaning, but no one has been able to give a definite interpretation to them. Confucius was greatly enamoured of these figures, and said that if he could devote 50 years to the study of these lines he might attain wisdom. The Yang and Yin principles represent the male and female element. They stand for heaven and earth, the sun and the moon, day and night, heat and cold, life and death, positive and negative, strong and weak, corresponding to Ohrmuzed and Ahriman of the Zoroastrians, Asiris and Isis of the Egyptians, the even and odd of Pythagoras.

The Five Elements.



The second doctrine is the five elements which are metal, wood, water, fire, and earth. The human frame is supposed to be made up of a harmonious mixture of these primordial substances. So long as the proportions remain proper, health exists; but if the balance is disturbed, disease follows. The five elements again interact on one another, thus:—

Metal generates water; destroys wood.
Water „ wood; „ fire.
Wood „ fire; „ earth.
Fire „ earth; „ metal.
Earth „ metal; „ water. (See figure.)

Corresponding with the five elements are the five organs—spleen, liver, heart, lungs, and kidneys—which are further related in a complex system of arrangements to the planets, colour, taste, climate, &c., according to the following scheme:—

	Organ.	Planet.	Element.	Colour.	Taste.	Climate.	Direction.
1	Heart.	Mars.	Fire.	Red.	Bitter.	Hot.	S.
2	Liver.	Jupiter.	Wood.	Green.	Sour.	Windy.	E.
3	Spleen.	Saturn.	Earth.	Yellow.	Sweet.	Moist.	C.
4	Lungs.	Venus.	Metal.	White.	Pungent	Dry.	W.
5	Kidney.	Mercury.	Water.	Black.	Salt.	Cool.	N.

S = South; E = East; C = Centre; W = West; N = North.

This reminds us of the humoral pathology of the Greeks, the Chinese system, however, being more complicated.

Classical Medicine.

Turning to the more strictly medical aspects of the classical epoch, the first authentic doctor who practised medicine and surgery appears to have been Pien Chiao, who lived about 255 B.C. Round him legends cluster. It is said that he could see through the human body, all diseases of internal organs being revealed—an anticipation of the X rays. In the Lietse the following story is related. Ching Wu of Lu and Tsi Ying of Chao were sick, and both asked Pien Chiao to treat them. He gave them a narcotic wine to drink which made them unconscious for three days. He opened their chests, exchanged their hearts, and when they awoke they felt as before, and took leave and returned home. This is the earliest record of the use of anæsthetics in China. But Pien Chiao is also regarded as the first exponent of taking the pulse which is considered indispensable by native doctors in diagnosis.

Massage has been practised in China from time immemorial. Its value is fully recognised, and in the Tang Dynasty it was elevated as a science, formed one of the seven departments of medicine, and at universities a special chair of massage was established with a professor in charge of it. But after the Sung Dynasty the practice degenerated till at the present day it is mostly in the hands of the barbers and the blind.

Acupuncture is a very old Chinese method. On the body 367 points of puncture are described, and more harm than good is done by its practice as asepsis is unknown to native doctors. The use of acupuncture spread early to Japan and, according to Remusat, it was introduced into Europe by Ten-Rhyne, a Dutch surgeon, at the end of the seventeenth century and was much extolled in France early in the nineteenth century. The late Sir James Cantlie and others tried it on sprains of joints and in chronic rheumatism and reported very favourably on it, and with further investigation it might prove a useful addition to our armamentarium. In the Imperial Academy of Medicine at Pekin there is still to be found a copper model of the human figure pierced with holes at the proper places for puncturing. The model is covered with paper and the student practises needling to discover a particular hole.

Anatomy and Dissection.—Because of the great reverence for the dead, human dissection was seldom attempted; hence gross mistakes are found in the Chinese conceptions of anatomy and physiology. But dissection was described in 2697 B.C. In the Lin Shu it is stated that after death the body may be dissected and observations made as to the size of the organs, the capacity of the intestines, the length of the blood-vessels, and so on. In the Han Dynasty Emperor Wang Mang captured a revolutionary and ordered his physician to dissect his body. Measurements were made of the internal organs and bamboo rods were inserted into the blood-vessels to see where they began and when they ended. Many records of this nature are in ancient literature, and about 2000 years before Harvey made his discovery of the circulation of the blood, the Chinese made a near guess at the story. For we find the following significant passages in the Canon of Medicine: "All the blood is under the jurisdiction of the heart. The 12 blood-vessels are deeply hidden between the muscles and cannot be seen. Only those on the outer ankles are visible because there is nothing to cover them in these places. All other blood-vessels on the surface of the body are 'loh' vessels (veins). The harmful effects of wind and rain enter the system first through the skin. It is then conveyed to the 'sun' vessels (capillaries). When these are full it goes to the 'loh' vessels (veins), and these in turn empty into the big 'chin' (arteries). The blood current flows continuously in a circle and never stops."

Examinations.—State medical examinations were held in China as early as the tenth century B.C. In the Chow rituals it is stated at the end of each year the work of the doctors was examined and the salary of each fixed according to the results shown.

Hygiene, General and Personal.—Sanitation was in a comparatively advanced state throughout much of this period. Wine-drinking was prohibited. The law against it was as stringent as the present prohibition laws are in the United States of America. There were special doctors to look after food and drink, dietitians, physicians, surgeons, and veterinary surgeons being the four classes of doctors. Temperance in the broad sense of the word was strongly advocated. The value of exercise was recognised. From experience the medical profession learned many laws of eugenics, though their real meaning was imperfectly understood, Many very sensible rules were laid down for prenatal care.

Hospitals.—These were established more than 600 years before the celebrated Basilian monasteries, yet in spite of such a good start the Chinese were slow to push their investigations into disease further: on the contrary, they lost sight of many of the valuable discoveries left them by their predecessors.

(*To be continued.*)

NEW CATALOGUE OF LEWIS'S LIBRARY.

THE new catalogue of Lewis's medical and scientific circulating library (136, Gower-street, London, W.C.1), which has proved indispensable to generations of students and medical men, has now been issued, revised to the end of December, 1927. It is published in two parts, conveniently bound together, of which the first (408 pages) is devoted to authors and titles arranged alphabetically and the second (166 pages) is a classified index of subjects with the names and initials of those authors who have written on them. To meet a suggestion made by critics of the last edition of the catalogue, now more than ten years old, the publishers state in a note to Part II. that authors' initials have been added to facilitate reference to the body of the catalogue. Unfortunately these are not uniformly supplied, and seem to be omitted in an undue proportion of foreign names where they are perhaps most needed. This is almost the only disappointment we have had in examining a catalogue that will be welcomed not only by subscribers but by men of science throughout the empire. In medicine and its allied sciences at least, it provides a list of publications in each subject which includes all the important works published in the English language. A bi-monthly list of new books and new additions is issued, so that subscribers are kept up to date. It is worth remembering that surplus copies of books withdrawn from circulation are offered at reduced prices. The catalogue is available to subscribers at 7*s.* 6*d.* and to non-subscribers at 15*s.*

NEW PREPARATIONS.

OLEOCAL: DRAGEES AND GRANULATE (Messrs. Wilcox, Jozeau and Co., Ltd., 15, Great St. Andrew-street, London, W.C.)—These two preparations of cod-liver oil in concentrated and solidified form are claimed by the Laboratoire des Produits Scientia, Paris, to contain the vitamins A, B, and D, salts of iron, and calcium and phosphorus. The great advantages of a form of supplying cod-liver oil which may be taken in all seasons and all climates with ready toleration need not be insisted upon. For adults the dose is 6 to 10 dragees, or 3 to 5 teaspoonfuls of the granulate each day in three doses with meals; for children the recommended dosage is 3 to 6 dragees according to age, or 1 to 3 teaspoonfuls of the granulate. The preparation may be broken up in the mouth or swallowed whole.

BAKOLYSE.—This preparation is distributed by the Anglo-French Drug Company, Ltd., 238A, Gray's Inn-road, London, W.C., and manufactured at the Sauvin laboratories in Paris, in accordance with the formula of Dr. Hervouet. It is a solution of amino-acids and creatinin for injection and in the hands of French physicians appears to have met, with success. The ampoules are supplied in boxes of ten, while the average dose is two ampoules weekly, the physician, however, watching the method of administration. The preparation is designed for states of malnutrition, especially tuberculosis. The formula seems to be a perfectly logical one, but the information supplied with the samples is not impressive.

ARCOLAX.—Messrs. Roberts and Co., 76, New Bond-street, London, W., call our attention to the properties of the seeds of psyllium plantago, which are sold by them under the name of Arcolax. The plant is found in the native state in many parts of the Mediterranean littoral, and the shining inodorous and tasteless little psyllium seeds, when ingested, expand to approximately four times their original volume. A quantity of mucilage is poured out, while the oil of the seeds is emulsified and fitted for absorption. The claim is that as a result, and without any interference with normal action, the mucous membrane of the intestine is lubricated and defæcation facilitated. Care has been taken that the seeds are sold in a clean state, and free from extraneous matter. The recommended dose for commencing a course of treatment for constipation is one teaspoonful, more or less as found necessary, in two or three times that quantity of water at bed-time. Arcolax is sold in boxes containing sufficient seeds to last a fortnight, if taken with the above dosage, while a point of some value is that the dose can be gradually reduced, and the times of administration spaced out until the preparation can be dispensed with.

PLASMONA.—This preparation, which is manufactured by Plasmon, Ltd., 66A, Farringdon-street, London, E.C., was analysed by us, and reported upon as recently as Dec. 15th last year. It claims to be a blood and nerve food containing the anti-anæmic principle of liver combined with lipoid compounds, together with the vitamin factors A, B, D, and E. We are informed that by a new process of manufacture a pleasant flavour is now imparted to the preparation, while its full strength is preserved. It may be mixed with either cold or warm milk, but boiling liquids should not be used as they destroy the efficacy of the preparation, which may be taken in place of tea, coffee, or cocoa.

GENOZO TOOTH PASTE.—We have received from Genatosan, Ltd., of Loughborough, Leicestershire, a specimen of this tooth-paste, which is designed to be antiseptic and therefore a preventive of pyorrhœa. The statement made by the firm as to the composition of a bacterial emulsion called Genovax is as follows: Streptococci, 15,000 millions per c.cm.; *M. catarrhalis*; 2000 millions per c.cm.; staphylococci, 2000 millions per c.cm.; *B. proteus*, 1000 millions per c.cm.; antiseptic content phenol, 0·5 per cent. Genovax is the "bacterial emulsion" alluded to in the formula for Genozo tooth-paste, which is given as glycerinum, 47·65; magnes. silic. and calcii carb. præcip., 49·22; bacterial emulsion and phenol, 0·76; ol. limonis and ol. menth. pip., 2·36; colouring, 0·01. The texture and flavour of the paste are very agreeable.

DIGIPAN; SICCOPAN.—These two preparations have reached us through the British agents, Messrs. Coates and Cooper, 41, Great Tower-street, London, E.C. For Digipan which is described as "physiologically standardised digitalis glucosides," it is claimed that through uniformity of composition and keeping qualities the drug can be used in a safe manner when the familiar indications for its employment are present. It is put up in solution, in ampoules, and in tablets by the manufacturers, the Temmler Chemical Works Berlin-Johannisthal, Germany, and is supplied to the medical profession only.

Siccopan is a nutritive food containing about 60 per cent. of dried hæmoglobin, with the addition of lecithin albumin, calcium lactate, and soluble silicic acid. The preparation is put up by the Sicco A.-G. Chemical Works, Berlin, which firm states that the slaughter-houses, whence the fresh blood is obtained, are in close proximity to their works, so that the process of drying can be carried out at a low temperature and fermentation avoided. The preparation might well be valuable in cases of anæmia and in convalescence after severe long illness or operation.

AT a special meeting of the Members of the Section of Odontology of the Royal Society of Medicine, held on July 17th, a bust of the late J. Howard Mummery was unveiled in the presence of the American Ambassador. The bust is a gift to the North-Western University, Chicago, from its London Alumni, and was formally received by Mr. A. D. Black, Professor of Dental Pathology in the North-Western University.

PAYING BEDS AT NEWCASTLE.—It is intended to provide a large number of beds for paying patients at the Royal Victoria Infirmary, Newcastle-on-Tyne. For this purpose three pavilions of the adjoining orthopædic hospital, which was recently taken over from the Ministry of Pensions, will be utilised, and it is expected that they will afford room for between 80 and 100 beds. The suggested charges will vary from 6s. per day upwards. At the moment the waiting-list of the Infirmary numbers 2000 persons.

An Address

[ABRIDGED]

ON THE

DEBT OF MODERN SURGERY TO THE ANCILLARY SCIENCES.

Delivered at the Annual Meeting of the British Medical Association at Manchester on Tuesday, July 23rd

BY ARTHUR HENRY BURGESS, M.B., M.Sc. VICT., F.R.C.S. ENG., D.L.,

PRESIDENT OF THE ASSOCIATION; PROFESSOR OF CLINICAL SURGERY, UNIVERSITY OF MANCHESTER; HONORARY SURGEON TO THE MANCHESTER ROYAL INFIRMARY.

[AFTER referring to the changes in the medical profession and in the hospital arrangements since the Association's visit to Manchester in 1902, and to the work of the 2nd Western General Hospital during the war, Prof. Burgess discussed the sharp dividing line between the history of surgery before and after the time of Lister. He explained how this extension had been particularly noticeable in the development of abdominal surgery. He gave a local illustration of this development by comparing the operations performed at the Manchester Royal Infirmary at the beginning and at the end of the first quarter of this century. During this period, the proportion of operations on the abdomen had risen from 11 per cent. to 57 per cent., the annual number of operations for acute abdominal conditions from 82 to 1241, while their total mortality had diminished from 36 to 8 per cent. Prof. Burgess continued :—]

This progress in surgery—which, I feel strongly, will compare favourably with that attained in any other branch of the arts and sciences—has not, nor could it have been, achieved without the material assistance of the contemporary advances in the allied sciences; it is, indeed, this which constitutes my main thesis to-night. Modern victories are rarely won single-handed, and the greater the number, the more effective the strength and the more vigorous the activities of the allied forces whence assistance is forthcoming, the more confidently may we look *forward* to a victorious issue. Prior to the time of John Hunter surgery was almost entirely an art—a glorified handicraft, taught and practised quite independently of all other arts and sciences, devoid of any physiological basis for its methods, and essentially empirical in its attempts at progress. Hunter, deeply imbued with the scientific spirit, introduced into surgery the method of careful observation, collection, and collation of facts, and their thorough testing by direct experimental investigation, rather than that of trusting to theories founded on insufficient and unproved evidence. "Don't think—try" was his favourite exhortation. He it was who first gave allies to surgery, urging that surgery should be regarded as a branch of natural science, to be studied in its appropriate relationship to all the other branches, thus bringing it into close association with chemistry, physics, biology, comparative anatomy, physiology, and pathology. Had the microscope been available in Hunter's day he would doubtless have added to these bacteriology.

Every important discovery in the natural sciences since Hunter's time has exerted its influence upon contemporary surgical thought and practice, and overwhelming indeed would be surgery's debt to its allies were it not offset by a corresponding counter-debt for the help rendered to them in return by the great advances that have been made in surgical knowledge.

Though the choice for consideration to-night of a few only of the numerous component factors of this debt of modern surgery to the ancillary sciences must necessarily prove an arbitrary and rather an invidious task, yet I feel that the concensus of surgical opinion will endorse my selection of physics and of physiology as the two sciences to which, in recent times, surgery is most indebted; and further, that of the many useful applications in surgery of the results of researches in physics three have established a special claim upon our attention—X rays, radium, and light therapy.

THREE APPLICATIONS OF PHYSICS.

1. *Radiology.*

The X rays, discovered by Wilhelm von Röntgen of Würzburg in 1895, were early applied to the diagnosis of pathological states in the human being, and thus was founded the science of radiology, whose subsequent brilliant achievements not only constitute one of the most important chapters of progress in medical affairs during the present century, but also open up vistas of still greater possibilities for the future.

The organs and tissues of the body vary in the degree of resistance they offer to the passage of the X rays, and it is upon the relative opacity of an organ to that of the tissues in its immediate vicinity that the possibility of demonstrating its shadow upon the radiographic plate or screen depends. The bones and teeth are very much more opaque than the soft structures, and cast the deepest shadows; the lungs are the most translucent, so that the heart placed betweem them is relatively opaque, and casts a very definite pulsating shadow. The kidneys are seen only to a very limited degree, since they are surrounded by tissues of approximately the same density as themselves; were they situated in the thorax their visibility would equal that of the heart.

Foreign bodies are displayable in proportion to their density, those of a metallic nature taking the first place. Had we not had available during the Great War the assistance of the X rays in the detection and accurate localisation of the bullets, shell fragments, and other metallic particles lodged in the tissues of so many of our wounded, war surgery would have had a very much less successful tale to unfold. Calculi are opaque to the X rays proportionately to the amount of lime salts they contain, those of the urinary tract being nowadays displayed with such reliability that operations for the removal of renal and ureteric stones are practically never undertaken unless the presence of the calculus has been previously radiographically demonstrated. In the bladder, it is true, stones are occasionally met with composed of uric acid only and quite translucent ("radiolucent") to the X rays; such may easily be overlooked even if of large size, but fortunately we have, in the cystoscope, a certain means of their recognition. Calculi in the salivary and other glands are readily displayed, while, with improving technique, gall-stones are being shown in a steadily increasing proportion of cases.

The assistance of the X rays in the diagnosis and treatment of fractures and dislocations has proved invaluable, and the advice given recently by the council of the Medical Defence Union in a circular letter to its members, to insist upon radiography in every case of suspected fracture, would appear to be extremely sound from several points of view other than the intended one of defence against a possible legal action for malpraxis. Radiography soon taught us that in a large proportion of what were formerly considered to be merely "sprains" of joints some definite bony injury was present, the overlooking and consequent failure to apply appropriate treatment to which explains the popular idea that a "sprain is worse than a break." Many incomplete and impacted fractures, and some of those without displacement, cannot be detected by any other means than radiography, and of this the general public is becoming aware. The public is, however, much too prone to estimate the success or failure of treatment of a fractured bone by the extent of the anatomical deformity displayed in the radiogram, rather than by the functional result; to the popular mind the "setting" of a fractured bone seems to imply that the radiographic picture should show the perfect apposition of the broken surface—an ideal which, though frequently most eloquently stressed by counsel for the plaintiff in an action for malpraxis, is, as the medical profession knows only too well, rarely attainable apart from open surgical operation.

X ray apparatus is now so efficient that the finest details of structure of the bones are easily shown, and the slightest changes therein induced by early disease can be readily detected. Thus the earliest manifestations of tubercle, of rickets, of syphilis, and of new growths as they affect bone are readily recognisable, and such knowledge conduces to earlier and more effective treatment. One of the commonest applications of radiography of the present day is that to the sockets of the teeth, and many a local source of origin of "local sepsis," otherwise inexplicable, has been thereby disclosed.

At an early stage of radiography its utility was vastly extended by the introduction of substances opaque to the X rays into parts of the body otherwise radiolucent, thus rendering them visible. The ramifications of sinuses in the soft parts were demonstrated radiographically by previously injecting them with bismuth paste. The introduction of the bismuth, and, later, of the barium meal has been *the* outstanding advance in radiology, and has completely changed many of our former ideas regarding the anatomical position, the form, and the physiological movements of the different parts of the alimentary tract, while it has added in a truly marvellous degree to our knowledge of their pathology. Radiology, to the infinitely greater safety of the patient, has entirely displaced the bougie in the diagnosis of œsophageal obstruction, and yields an accuracy of information as to the exact situation, extent, and nature of the cause of the obstruction previously quite unattainable. It thus differentiates readily between simple cicatricial stricture, malignant stricture, compression of the œsophagus by tumours from without, and the very imperfectly understood muscular obstruction at its lower end, to which the term "cardiospasm" is applied. The presence, situation, size, and shape of pharyngeal and œsophageal diverticula are demonstrated with certainty by means of the opaque meal, which has also taught us that diverticula of the alimentary canal, though most frequently met with in the pelvic colon, may occur also in the rest of the large intestine, in the appendix, the small intestine, the duodenum, and even in the stomach. The recognition of gastric and duodenal ulcers, of their complications, such as hour-glass contraction and pyloric stenosis; of gastric cancer, more particularly in its earlier stages; of obstructions of the intestines, especially that of carcinoma of the colon, by means of the opaque enema, either alone or in combination with the opaque meal; of displacements of the viscera such as are observed in diaphragmatic hernia or in visceroptosis, and the demonstration by Graham's method of the outline of the gall-bladder some 10 to 12 hours after the administration of tetraiodo-phenolphthalein, owing to the power of this viscus to concentrate the bile, in which the drug is excreted, to such a degree as to prove opaque to the X rays—all these constitute veritable triumphs of radiology, and have enormously facilitated the diagnosis of abdominal conditions.

Much the same may be said of the application of the opaque ureteral bougie and of the introduction of opaque media into some part of the genito-urinary tract during radiography—pyelography, ureterography, cystography, or urethrography, according to the portion of the tract concerned. Of these, pyelography has been most employed, and has disclosed alterations in the size, shape, and position of the renal pelvis, calyces, and ureters which have proved of the highest possible value in the diagnosis of renal pathological states.

The introduction into the trachea of the opaque medium lipiodol—a combination of 40 per cent. iodine with oil of poppy seeds—renders the bronchi and their ramifications visible upon a radiogram taken very shortly afterwards, and has been found useful in determining the relation of a foreign body in the lung to the nearest accessible bronchus, in demonstrating the outlines of lung abscesses, the presence and extent of bronchiectasis, the existence of a broncho-pleural fistula, and the extent of malignant growths involving the bronchi. Lipiodol was originally recommended by Sicard of Paris in 1921 for the localisation of the site of blockage of the subarachnoid space by spinal cord tumours. Introduced into the upper part of this space, as by injection into the cisterna magna, the medium falls by gravity to the level of the upper limit of the obstruction, and can there be radiographically shown. By injecting into the lumbar sac an "ascending" mixture of lipiodol and olive oil, of lighter specific gravity than the cerebro-spinal fluid, the lower extent of the subarachnoid block can be defined. The method is not altogether devoid of danger, and lipiodol once introduced, appears to remain unabsorbed for a long period, even for years. The injection of lipiodol into the uterine cavity has been used to indicate its size and shape, and any encroachment upon it as by a growth, while the failure of the medium to pass along one or both Fallopian tubes has been utilised in the diagnosis of their obstruction in cases of sterility.

Another method of altering the relative densities to X rays of adjacent soft structures, and thus rendering their outlines visible, is the introduction of a gaseous medium—air, oxygen, or carbon dioxide—as into the perirenal tissues, thereby allowing the outline of the renal shadow to be readily discerned; or into the peritoneal cavity, when the liver, spleen, and kidneys are rendered visible. The withdrawal by puncture through a drill hole in the skull of a small amount of fluid from one of the lateral ventricles of the brain and its replacement by air or oxygen has allowed the outlines of the ventricles to be rendered visible upon the radiographic plate; their increased size in internal hydrocephalus can thus be readily demonstrated, whilst the position relative to the ventricle of an otherwise obscure cerebral tumour can often be accurately ascertained.

The growing importance of radiology is evidenced by the steadily increasing proportion of patients who pass through the X ray department of our hospitals either for diagnosis or treatment. At the Manchester Royal Infirmary this proportion has gradually risen from 1 in 100 in 1908, to 1 in 24 in 1912, 1 in 11 in 1917, and 1 in 5 in 1928.

2. *Radium*

Radium was discovered in 1898 by Prof. and Madame Curie in a deposit of pitchblende from Joachimstal in Bohemia, and was at first a monopoly of the Austrian Government. This monopoly was transferred to the American Government in 1913 owing to the discovery in Colorado and Utah of carnotite—a mineral which, although the proportion of radium it contained was as small as 1 gramme in 400 tons, nevertheless proved profitable to work owing to the ease with which the radium could be extracted. The finding of some very rich lodes of pitchblende in the Belgian Congo in 1921 has now placed the monopoly in the hands of a Belgian syndicate, who, in their factory at Oolen, at present supply most of the world's demand. It requires from 30 to 40 tons of ore to yield 1 gramme of radium, and its extraction necessitates spacious premises, much labour, and many highly skilled operatives, all these factors being reflected in the present market price of about £12,000 per gramme. This monopoly seems likely to persist for some time, and only the discovery of a new source of really rich deposit can ameliorate the present situation.

Radium emits rays of three varieties—alpha, beta, and gamma—the last, similar to the Rontgen rays, and of high penetrative power, being those mainly used in deep treatment. Upon both animal and vegetable life radium has a decidedly detrimental effect, which is not, however, exercised equally upon all tissue cells, and even upon normal tissues radium has a decidedly selective action. Thus the cells of glandular structures, especially those of the ovary and testis, are much more susceptible than those of fibrous tissue, while muscle, cartilage, and nerve-cells are the least sensitive. Actively dividing cells are the most vulnerable, and the cells of malignant growths, in which activity of cell division is a prominent feature, are more readily affected by radium than the other cells of the body. Upon this selective action the therapeutic value of radium in cancer depends, and our problem is to determine the exact dose that will exert the maximal destructive effect upon the cells of the malignant growth with the minimal upon those of the other tissues. There is a minimal dose below which no destructive action occurs, and many believe that these weak irradiations can stimulate the growth of tumour cells, and even stir into activity cells actually quiescent. The total dosage of radium, calculated in milligramme hours, can be applied either as a large amount of radium acting for a short time, or a small amount acting for a long time, and opinion is not yet decided upon the optimal dosage for each type of growth. On the one hand, by prolonging the duration of exposure, a greater number of cells will be adversely influenced during the vulnerable stage of active cell division; on the other hand, it has been shown experimentally that repeated sublethal doses may actually increase the resistance of the tumour cell to radium, and radiation treatment should, therefore, be concluded within a reasonably short time, and not indefinitely repeated.

As a therapeutic agent radium has been found of considerable value in non-malignant conditions—such as nævus, keloid, lupus and other skin diseases, exophthalmic goitre, and benign tumours—but it is in the treatment of malignant disease (including rodent ulcer) that its chief interest to us lies. Restricted at first entirely to cases too advanced for radical operative treatment, its scope has within the last few years been extended, either alone or in combination with surgery, to the treatment of operable cases. There has arisen a special branch of surgical technique —"the surgery of access"—concerned with the planning of operative procedures for the appropriate exposure of deeply seated malignant growths in order that radium tubes may be placed in correct relation thereto—as when a rectal carcinoma is exposed by removal of the coccyx and lower portion of the sacrum, an œsophageal carcinoma through the posterior mediastinum after rib resection or across the pleural cavity by lateral thoracotomy, or an intralaryngeal growth through a "window" cut in the thyroid cartilage. Modern methods of radium application have met with such considerable success in cancers of the skin, of the cervix uteri, of the mouth and tongue, and of the larynx, that there is an increasing tendency in these cases to prefer radium to operative treatment, at any rate so far as the primary growth is concerned. The comparatively slight disturbance of radium tube insertion, or of radium bomb treatment, their lesser risks, and the absence of that mutilation necessarily associated with a radical surgical operation, and which, as in the case of the tongue, may prove a considerable and permanent disadvantage, are factors favourable to radium, and should tend to overcome the natural reluctance of the average patient to submit to early treatment. It is, however, upon the end-results that the question must be ultimately decided, and these are not yet sufficiently known in the case of radium for a conclusive judgment, although some promising series of five-year statistics have been reported. In many cases the best results are obtained by a combination of radium treatment with surgery, as when the radical operation for cancer of the breast is associated with the implantation of radium tubes or needles into the supraclavicular and anterior mediastinal regions. At the present moment expert opinion seems to favour reversion to the external application of radium, either alone or in combination with radium tube insertion and very short wave-length X ray irradiation. There are, however, two most important changes from the surface applications as originally practised: (1) the much larger quantities of radium used—up to 4 g., and (2) the much greater distance from the skin—as much as 10 cm.—at which it is applied, thereby ensuring a more uniform dosage to all parts of the area irradiated, with lessening risk of cutaneous damage. This "bomb" or "cannon" treatment—as at present carried out in Paris, Brussels, Stockholm, and on a smaller scale at the Westminster Hospital, London—is considered by many likely to prove the method of choice in radium therapy, and it certainly deserves to be tested very thoroughly, should a sufficiency of radium be forthcoming. The still very high cost of radium in spite of the removal of the one-third *ad valorem* Government duty, and its restricted supply, are matters requiring urgent attention, and every means must be taken not only to increase its production, but also to ensure that the most efficient and most economical use is made of such supply as is already available, having regard to the absolute necessity, in this connexion, of maintaining an intimate association between treatment and research. The technique of radium therapy is highly specialised, and such work should be centralised and restricted to the expert staffs of special institutions established in a few of the largest cities of a country. Until the supply of radium becomes less inadequate to cope with the increasing demand it may be advisable to arrange for a "night" as well as a "day" staff of workers at these institutions in order to minimise the number of hours ("radium-hours") during which any of the radium is unemployed in treatment.

3. *Actinotherapy.*

Heliotherapy—treatment by sunlight—is probably as old as human history. Hippocrates (460 to 370 B.C.), refers to the effect of sunlight in promoting health, and recommends sufferers from various ailments to walk about naked in the sun as much as possible—a simple remedy, which seems, however, to have been overlooked for many subsequent centuries. At the end of the last century a considerable proportion of the beds in the hospital wards of our large cities was occupied with cases of tuberculous disease of the bones, joints, and spine, and other forms of "surgical" tuberculosis, for which operations, often of a very extensive and mutilating nature, and frequently requiring repetition, were considered the only chance of a cure. How frequently they failed, and, even when successful in saving life, the unsightly deformities and fearful defects of function that resulted are some of the unpleasant memories of those of us who practised at that time. No more beneficent change has occurred in any department of treatment than in that of surgical tuberculosis during the past quarter of a century.

Thanks to the pioneer work of Bernhard and Rollier in Switzerland, and of Sir Henry Gauvain and Sir Robert Jones in this country, these mutilating surgical operations are things of the past. Surgical tuberculosis is nowadays treated by a general exposure of the body to sunlight in the open air in summer, and to artificial sunlight in the winter or whenever natural sunlight is not available. This should be combined with local treatment so designed as to ensure complete immobilisation of any active focus, the removal of any pressure or weight-bearing, the correction, so far as is possible, of any existing deformity, and the [illegible] care of any discharging sinuses. Active surgery is limited almost entirely to the evacuation of any cold abscesses that may develop, although in tuberculous spinal disease operations (Albee's, Hibbs's) are occasionally performed, not as a direct attack on the affected tissues, but to ensure better immobilisation of the morbid focus in the vertebral bodies by bony ankylosis of the spinous processes of the affected vertebræ and of those immediately above and below. Under this modern plan of campaign [illegible] [illegible]y assured in a much greater [illegible] [illegible] the bronzed and [illegible] [illegible] [illegible]der sunlight treatment [illegible] [illegible] waxen faces and wasted days, while the local focus of disease heals with the minimum of deformity and the maximum preservation of function.

Treatment by ultra-violet radiation (actinotherapy) is now being extended to rickets and other general diseases, to most forms of skin disease, and to many disorders of the circulatory, respiratory, alimentary, nervous, and genito-urinary systems, as well as to those of the special senses. It has, in fact, assumed the dimensions of a "boom" treatment, and "sun-ray" centres are being established all over the country, not only as private ventures, often controlled by laymen only, but also at the municipal bathing establishments of many of our cities and towns, while there are sunbaths in many factories and at "pitheads" in several of our coal-mining districts.

The ultra-violet rays are, however, far from being innocuous, and their correct dosage is a matter of great importance and of careful individualisation, since what is a safe dose for one may be dangerous to another. Over-exposure to their influence produces sleeplessness, restlessness, loss of weight, lassitude, and even sickness, while severe burns and serious forms of dermatitis may result in sensitive persons. Moreover, some ailments are adversely influenced by ultra-violet ray treatment—notably chronic nephritis, arteriosclerosis, and quiescent tuberculosis, the last of which may easily be stirred into renewed activity. It is therefore in the public interest that the prescription of ultra-violet rays be restricted to the medical profession, and that their application be undertaken only by those who have received a proper course of training for this special work.

In view of the risks to the public involved in the use of electricity and radiation as methods of treatment by untrained and unqualified persons, the Representative Body of the British Medical Association, at the last annual meeting, expressed the opinion that suitable courses of training should be organised under medical direction for persons wishing to administer this form of treatment; that persons who have satisfactorily followed such a course should be entitled to have their names entered on an approved roll; that they should undertake to treat only patients sent to them by medical men, and that medical men should refer their patients only to those persons whose names are on the approved roll. Along these lines the Society of Apothecaries of London, acting in concert with the British Medical Association, has recently agreed to set up a standard to which persons practising physiotherapeutic treatment should attain, to institute a diploma, and to establish a register of those found qualified to serve as "biophysical assistants," such registration to entitle the appendage of the letters "B.P.A." to their names. The unqualified, unregistered chemist, dentist, and midwife are forbidden by law, and it seems only logical that the unqualified electrotherapist, who handles therapeutic measures equally potential of danger, should be placed under similar legal control.

PHYSIOLOGY: THE ESSENTIAL FOUNDATION OF MODERN MEDICINE AND SURGERY.

Physiology has often been referred to in the past as the handmaiden of medicine, but such a description very inadequately represents its present status as a proud and independent branch of true science—the science of life itself. Rather must it be described as the essential foundation of modern medicine and surgery, as the means by which many of our former purely empirical methods of treatment have been placed upon a rational basis, and as the main factor by which the practice of medicine and surgery is daily becoming proportionately more of a science and less of an art. That the element of art must continue permanently to play a considerable part in surgery is self-evident when we remember how largely handicraft enters into its daily routine, but the merely artistic aspect of surgery has now, we may fairly claim, been brought to so high a degree of perfection that it is not so much upon outstanding advancements in surgical artistry that we must rely for future progress as upon a more thorough understanding of the physiological principles involved in our work, and their application to what is, after all, the great aim of surgery—the restoration of deranged function to the normal. The greater comprehension the surgeon obtains of what constitutes normal function the better equipped is he to achieve this aim, and to improve his methods by means which were not possible in the days when physiology was less advanced. The surgeon and the physiologist must tread the path of progress hand in hand, to the great advantage of each, since the debt between them is essentially a mutual one. For the success of his experiments upon animals the physiologist has to depend largely upon the methods of modern aseptic surgery, and has, therefore, a very vital interest in any improvements in surgical technique that may from time to time accrue. Moreover, though it is true that many discoveries made by physiologists which have found valuable practical application in medicine and surgery have originated purely in the search after truth and without any thought of their possible clinical utility, yet, on the other hand, there are many instances where clinical observation has been the starting point of physiological researches which have ultimately proved of the greatest benefit in the treatment of human disease. One of the most impressive illustrations of this is yielded by the development of our knowledge of the localisation of function in the cortex of the brain.

[Prof. Burgess gave a historical survey of the progress made in the localisation of cerebral function, and in our knowledge of the functions of the thyroid gland.]

New Methods of Study.

The progress of physiology during the present century has been characterised by many new methods of study, by the greater attention devoted to human physiology, and by the enormous strides made in the physiology of nutrition. If we look back to the beginning of this century and compare the state of physiological knowledge then with that of the present day it is wonderful to contemplate the discoveries that have been made. The use of X rays for the examination of the function of the stomach and small intestines, developed first of all by Cannon for physiological purposes, had only just begun to be applied to the diagnosis of alimentary diseases. The rôle of proteins in nutrition was imperfectly understood and their chemical constitution was only a conjecture. Vitamins had not been heard of. Insulin was still a hypothetical substance. None of the active principles of the ductless glands had been synthesised and their mode of action was very incompletely known. Micromethods for the biochemical examination of the blood and other body fluids were practically unknown. The buffering mechanisms of the blood were not dreamt of, and the close interplay between normal physiological functions such as secretion and respiration, and their part in the regulation of body neutrality, was not known. The relation of the capillary circulation to the production of shock is also a relatively recent discovery.

All these advances in knowledge, and many others that might be mentioned, have had their influence on surgery—directly, because they have improved methods of diagnosis and treatment, and indirectly on account of their influence on the attitude of the surgeon to his subject. It is impossible to deal in detail with each particular advancement which surgery owes to physiology, but a few examples may be mentioned.

[Prof. Burgess then outlined the pioneer work of Gowland Hopkins on vitamins, and of E. Mellanby on dietetic deficiencies leading to rickets, and traced the effects in medicine of the discovery of vitamin D in certain foodstuffs, and of its production by irradiation of ergosterol. He spoke of blood transfusion as one of the most useful of our emergency surgical therapeutic measures, which had been reintroduced on a sound physiological basis, when its dangers had been eliminated by the differentiation of the four now well-known blood groups. Another triumph of physiological research, which was useful to the surgeon as to the physician, was the isolation and standardisation of insulin. No patient was now refused any necessary operation because of diabetes, the mortality of operations upon diabetics had been reduced to that in cases without this complication, and it seemed likely that in the future, with a better knowledge of the part played by insulin in carbohydrate metabolism, it might find other surgical uses.

Prof. Burgess then discussed at greater length the physiology of the kidney as applied to surgical problems:—]

Assessment of Renal Function.

It is principally to the painstaking and persevering work of the American biochemist Folin that we owe the modern micro-methods of blood analysis whereby, using only a few cubic centimetres of blood, all the important constituents can be accurately determined. These methods have been particularly helpful in cases where prostatectomy is contemplated and where it is essential to know to what extent the excretory functions of the kidneys have been already adversely affected by back-pressure from the prostatic obstruction, as indicated by the abnormal retention in the blood of urea, uric acid, creatinin, and other waste products to an extent varying directly with the degree of renal derangement. It cannot, in fact, be too strongly stressed that the operative risks of prostatectomy are concerned infinitely more with the condition of the kidneys than of the prostate, and that by delaying the major operation until the renal functions have been improved by the relief from "back-pressure" afforded by adequate preliminary drainage of the bladder—either by the indwelling catheter or by suprapubic cystostomy—the dangers attending the removal of the prostate can be very materially diminished. Biochemists, by means of their tests of renal functional capacity, have enabled surgeons to estimate the power of the kidneys to withstand surgical intervention with a degree of accuracy that is truly remarkable. Would that the same could be said of the liver, and that we could "size-up" the functional state of that organ as simply and as correctly as we can that of the kidneys. So manifold and varied, however, are the functions of the liver, and so diverse the directions in which deranged hepatic function may become clinically manifest, that any reliable estimation thereof must necessarily involve more extensive and more complicated procedures than in the case of the kidneys.

Of other methods of applied physiology to which the surgeon is indebted, mention may be made of the use of fractional gastric analysis for investigation of the activity, both digestive and motor, of the stomach; the duodenal tube for the collection and examination of bile; estimation of the basal metabolism as a guide to over- and under-activity of the thyroid and pituitary glands, and to the nature of the operative procedures to be undertaken in connexion therewith; determination of the carbon dioxide combining power of the blood and its relation to the diagnosis of those conditions of acidosis and alkalosis that occasionally complicate surgical procedures; and the examination of the red blood corpuscles for "fragility" in cases of splenic enlargement, as in haemolytic jaundice.

In the past a large proportion of the discoveries of physiology has been the outcome of experiments upon animals, conducted in physiological laboratories, while the wide field for the investigation of its problems offered by the hospital wards and operating theatres has been comparatively little utilised. For the elucidation of many points man himself possesses many advantages over the lower animals as a subject of investigation, and a more active encouragement of clinical research in human physiology is one of the prominent needs of to-day. In Manchester the University professor of physiology has been placed along with his colleagues in anatomy, physics, and pharmacology, upon the consulting staff of the Royal Infirmary, so that the closest possible connexion is maintained between these ancillary sciences and the clinical aspects of medicine and surgery.

Application to the Human Machine.

Pregnant with promise, too, is the recent extension of physiological research to the whole field of human activity. Laboratory investigations have taught us much of the physical and chemical workings of the individual systems of the human body, and have supplied us with various measures by which these can be tested. But of the workings of the human machine as a whole under the varying conditions and stresses of industrial and other forms of activity comparatively little was known. Early in the war it was recognised that the methods of medical examination of recruits then in vogue were far from satisfactory, and their inefficiency was frequently shown up on the parade ground and in the training camps. Especially was this so in the case of individuals in the Royal Air Force, where it was soon recognised that perfectly "sound" men, in the usually accepted medical sense, might nevertheless be quite unfitted to control an aeroplane. New and more delicate tests were required of the functional activity of the various systems, especially the visual, circulatory, and nervous systems, and of their quickness of response to the constantly changing conditions met with in flying. The medical officers of the Royal Air Force have shown most praiseworthy ingenuity in devising methods for the more efficient testing of the body functions, and have given a great impetus to the study of the healthy human machine at work under conditions hitherto unknown. In the field of industry it is becoming more generally recognised that the test of health is the capacity to perform effective work, and researches are constantly being made into the effects of environmental factors—for example, fatigue, monotony, noise, high illumination—upon the productive efficiency of the industrial worker. It has been shown that the distribution of industrial accidents amongst workers exposed to similar conditions of risk is not a mere matter of chance, but that each has an individual proneness to accident which can be fairly exactly estimated by testing the rapidity and accuracy with which he reacts to certain visual, auditory, and tactile stimuli. Though much still remains to be accomplished, the valuable information thus acquired has already brought about vast improvements in working conditions in many of our industries, and in the standard of health and the productive capacity of those employed therein.

OTHER ANCILLARY SCIENCES.

Of modern surgery's debt to the other ancillary sciences that to bacteriology is assuredly the most fundamental, since it was Pasteur's discovery that fermentation and putrefaction were caused by minute living organisms and were, therefore, vital and not merely chemical processes, as hitherto believed, that led Lister to his great conception of the antiseptic treatment of that putrefaction then found in almost all wounds—a conception which constitutes, as we have seen, the very starting-point of modern surgery. Time permits me merely to mention other advances in bacteriology: the detection of the causative germs of almost all the infective diseases; the elucidation of the great principles of immunity, both "active" and "passive"; the preparation of vaccines and of antitoxic serums and their use in the prevention and treatment of bacterial infections; the therapy of systemic infections by the intravenous introduction of chemical antiseptics resulting, among other notable gains, in that brilliant conquest of the former scourge of syphilis that has been achieved within the present century—all of which constitute milestones along the highway of bacteriology's triumphal progress.

Nor have I time to refer to the great help that modern surgery has received from research workers in anatomy, pathology, and pharmacology, valuable as their contributions have been; nor yet to more general sources of assistance such as the greatly improved means of rapid intercommunication (the telephone, the wireless) and of rapid transport (the motor-car, the aeroplane), factors which have so materially facilitated the prompt application of surgical relief in cases of emergency, whether on land or at sea.

I trust, however, that enough has been said to indicate that modern surgery, with the aid of its allies, has made, and is still making, great progress towards that end we all so fervently desire—the prevention of those abnormal conditions, the late results of which to-day necessitate so much surgical attention of a destructive rather than a constructive character. Much yet remains to be done, and the natural sciences must continue to advance, each ready to assist and to accept assistance from its fellows, each along its own special path yet all in mutual friendly alliance working for the common good, all in zealous pursuit of that goal, unattainable though it must ever remain, that will-o'-the-wisp of perfect knowledge and complete understanding. In so doing they will but follow the precept and the spirit of that motto upon the crest of our beloved University, in whose venerable precincts this great Association will to-morrow enter upon its full scientific programme, and of which we in this city are all so intensely proud; "Arduus ad solem"—"leaping upwards to the sunshine"—"ever striving towards the very highest."

ON THE

Clinical Classification

OF

CONGENITAL CARDIAC DISEASE.*

BY MAUDE E. ABBOTT, M.D. McGILL.,
ASSISTANT PROFESSOR OF MEDICAL RESEARCH, MCGILL UNIVERSITY, MONTREAL.

CLINICIANS do not always recognise the fact that congenital cardiac disease does not necessarily mean "blue baby" or *morbus cæruleus*, with its familiar symptom-complex of cyanosis, dyspnœa, and clubbing, and its progressively downward course. This condition gives little scope for the physician's skill, since the deficient oxygenation of the blood thus revealed is the result of unalterable structural changes in the heart. On the other hand, there exists a larger and clinically a much more important group of congenital cardiac patients to whom the word "acyanotic" applies, for the reason that these patients do not, under otherwise normal conditions in the body, present any raised oxygen-unsaturation at all, so that they show either no cyanosis, or cyanosis only as a transient or very "late" phenomenon. In this group are included those congenital lesions in which *no abnormal communication* between the two circulations exists, so that venous blood does not enter the arterial stream as a result of the anomaly—e.g., coarctation of the aorta—and also the localised cardiovascular septal defects, in which, in the absence of complications and under the physiological conditions of relatively higher pressure in the systemic circulation, blood passes from left to right through the defect. In these cases an *arterial-venous shunt* exists, which may, in the event of a pathological rise of pressure in the right chambers, be temporarily converted into a venous-arterial shunt, with the appearance of *transient* or *terminal* cyanosis.

ACYANOTIC CASES.

These so-called "acyanotic" cases are of great importance to the clinician, for such patients have a relatively good expectation of life, and may live to an advanced age without showing any sign of being hampered by their anomaly. On the other hand, the defect is almost always the seat of strain, and this renders these subjects peculiarly liable to serious complications, especially infective endocarditis or endarteritis usually of the subacute bacterial form, which commonly involves the margins or neighbourhood of the defect, and usually has a lethal termination; or, in another set of cases, the wall of the aorta may undergo spontaneous rupture, either from a concomitant congenital thinning of its coats, or from increased intra-arterial tension; or the myocardium itself may fail, leading to cardiac insufficiency or to the conversion of an arterial venous into a venous-arterial shunt. The fact that these acyanotic congenital lesions do present a fairly good prognosis in the absence of the grave complications which threaten them, makes their early recognition and the rigid preventive care of such patients imperative. The American Heart Association classifies patients with healed rheumatic lesions as "potential cardiacs," and prescribes for these the removal of foci of infection, proper rest, and careful supervision with a view to the avoidance of undue strain, and the elimination of unnecessary risks. It is surely desirable that acyanotic congenital cardiacs should be similarly classified, and as carefully safeguarded and watched.

DIAGNOSIS.

A congenital cardiac lesion of the acyanotic group may usually be "picked up" by detecting, in an otherwise apparently normal individual, the presence of pulsation murmur or thrill of unusual localisation and character in the cardiovascular area. Incidentally, these people often display the slender habitus characteristic of the hypoplasia of the aorta often associated with this congenital lesion. With the help of X rays a further differential diagnosis can often be made between such classic conditions as coarctation of the aorta, subaortic stenosis, and the various forms of cardiovascular septal defects (patent ductus, maladie de Roger, and so forth). In infants under one year, however, practically no differentiation into "cyanotic" or "acyanotic" types can be made with certainty because, excepting the most complex cases of extreme morbus cæruleus, cyanosis often does not manifest itself until after many months of postnatal life. So that one must here be content as a rule with the mere recognition of the presence of a congenital lesion, until sufficient time has elapsed after birth for the manifestation of cyanosis after the "threshold-value" of raised oxygen-unsaturation is reached.

THE CYANOTIC GROUP.

A word may be added regarding the diagnosis of the cyanotic group, though this is of much less practical importance. Once infancy is past, these subjects are readily recognised by their very striking symptomatology, especially the cyanotic hue, which deepens on exercise; and when to these appearances are added atypical physical signs over the cardiac area the presence of a morbus cæruleus is readily established. Differentiation of the exact lesion present in such a cyanotic case can scarcely be determined with certainty, but only a few combinations survive into adult life (see classification below), and of these that most commonly met with in cyanotic patients reaching early adult life is the "tetralogy of Fallot" (pulmonary stenosis, with associated ventricular septal defect and dextroposition of the aorta). These conditions exist in at least 75 per cent. of cyanotic young adults with congenital lesions. In cyanotic patients living beyond middle life one may suspect complete defect of the interventricular septum (cor triloculare biatriatrium) or pulmonary stenosis with closed interventricular septum, since statistics show that the average duration of life in these cases is relatively long.

CLINICAL CLASSIFICATION.

Under the classification set out below, which I have elaborated in the section on Congenital Cardiac Disease in the third edition of Osler and Macrae's

---

* Abridged from an address delivered at the New Sussex Hospital, Brighton, on July 20th, 1929.

"Modern Medicine" (London, 1927), the principal cardiac anomalies are grouped in the order of their clinical importance.

A. Of Clinical Significance.

I. *Non-cyanotic Group.*

1. Cases in which no abnormal communication exists, but in which the defect may produce a *mechanical interference* with the circulation which become the seat of strain. These are: pericardial defect; ectopia cordis abdominalis; primary congenital hypertrophy; congenital heart-block; anomalous septa; pulmonary and tricuspid insufficiency; aortic and mitral stenosis; anomalies of semilunar and auriculo-ventricular cusps; coarctation and hypoplasia of the aorta; anomalies of the aortic arch; anomalies of coronary arteries; congenital arteriovenous aneurysm; certain anomalies of veins and anomalies of pulmonary artery.

2. Cases of *arterial-venous shunt* with possible terminal or transient reversal of flow (*cyanose tardive*): (*a*) Defects of the interauricular septum (persistent ostium primum; persistent ostium secundum; patent foramen ovale; multiple defects; complete defect (cor-biventriculare triloculare). (*b*) Localised defects at the base of the interventricular septum (*Maladie de Roger;* defects below; multiple). (*c*) Patent ductus arteriosus and localised defects of aortic septum (communication just above the aortic valve; congenital aneurysm of the right aortic sinus of Valsalva).

II. *Cyanotic Group.* (*Morbus cæruleus.*)

1. Cases of *venous-arterial shunt* (arranged in order of severity of shunt). (*a*) *Moderate cyanosis:* Dextroposition of aorta with defect at base of ventricular septum; complete absence of ventricular septum (cor biatriatrium triloculare); pulmonary stenosis of inflammatory type with closed ventricular septum and patent foramen ovale; tricuspid atresia with interauricular septal defect and transposition of the great trunks. (*b*) *Marked cyanosis:* Pulmonary stenosis with dextroposition of aorta and interventricular septal defect (tetralogy of Fallot); pulmonary atresia with ventricular septal defect, dextroposition of the aorta, and patent ductus; transposition of arterial trunks with ventricular septal defects and dextroposition of the aorta. (*c*) *Extreme cyanosis:* Complete absence of cardiac septa (cor biloculare); complete defect of aortic septum (persistent truncus); transposition of arterial trunks with patent foramen ovale and patent ductus but closed interventricular septum: pulmonary atresia with closed ventricular septum, patent foramen ovale and patent ductus; aortic and mitral atresia with defect of interventricular septum and aplasia of aorta.

2. *Cases of Raised Peripheral Pressure. Right-sided valvular lesions* with closed septa (pulmonary and tricuspid stenosis).

B. Cases of No Clinical Significance.

Diverticulum of pericardium; bifid apex of heart; diverticulum of heart; acardia, ectopia cordis pectoralis (non-viable); congenital rhabdomyoma; true (mirror-picture) dextrocardia.

[Dr. Abbott demonstrated with an epidiascope diagrams illustrating the course of the circulation in the different defects, and photographs of the corresponding pathological specimens.]

THE BACTERIOLOGICAL DIAGNOSIS OF WHOOPING-COUGH.

By H. SUGARE, M.D. Leeds,

and

J. W. McLEOD, M.B. Glasg.,

BROTHERTON PROFESSOR OF BACTERIOLOGY IN THE UNIVERSITY OF LEEDS.

Since the original work of Bordet and Gengou (1906), in which they demonstrated the existence of a bacillus morphologically similar to, but distinct from the influenza bacillus, in the sputum of patients suffering from whooping-cough, there has been very little attempt, except in Denmark, to make a practical application of these findings. The medical profession has not resorted to the bacteriological diagnosis of doubtful whooping-cough. The reasons for this may be that a certain scepticism still prevails about the ætiological connexion of the bacillus which these observers described with this disease and that it has not been realised that the differentiation of this bacillus from the influenza bacillus is easily made.

Observations such as those of Wollstein (1909) and Scheller (1912), who found difficulty in repeating Bordet's serological observations in the disease, have probably contributed to this scepticism, and many of the statements in the text-books and elsewhere leave the impression that the differentiation between *B. influenzæ* and *B. pertussis* rests on some relatively fine points—e.g., Andrewes (1920), in discussing the influenza group of bacteria, says, "Many bacteriologists would agree that we may be confounding under the common term, *B. influenzæ*, a number of closely related species. Bordet's 'whooping-cough bacillus' would fall into such a group."

It is one of the purposes of this paper to emphasise afresh the facts already indicated by Bordet and more recently stressed by Kristensen (1922) that although these bacilli are probably related species there is little ground beyond that of microscopic morphology for confusing them. In the examination of the thick whitish exudate expectorated in the early stages of the disease, Bordet and Gengou demonstrated the presence of a small Gram-negative ovoid microbe, constant in size and appearance (1906). The medium used for successful cultivation was blood-agar with a basis of glycerinated extract of potato (1907). Even on this special medium their organism grew remarkably slowly, two–three days elapsing before the colonies appeared. In the examination of specimens of sputum from patients who had been affected with whooping-cough for some time, Bordet and Gengou found in almost every case and apart from the *B. pertussis*, an organism identical with or very similar to the bacillus found by Pfeiffer in cases of influenza. It was, however, smaller than *B. pertussis* and it showed a marked tendency to pleomorphism and to the development of involution forms. Bordet and Gengou also showed that this organism was met quite frequently in other respiratory affections besides whooping-cough. In a series of papers published subsequently Bordet elaborated and confirmed his original observations with Gengou on the morphological and cultural characters of the *B. pertussis* found by them in early cases of whooping-cough (1907, 1908, 1909 and 1912).

Kristensen (1922) has drawn attention to two additional points of contrast between these bacilli: (1) the capacity of *B. pertussis* to survive for considerable periods on suitable media at low temperature, a character lacking in *B. influenzæ* in his observations, and (2), more important still, the inability of *B. pertussis* to grow freely on the media best adapted for the growth of *B. influenzæ*, such as Levinthal's, "chocolate agar," &c. Convinced by these and other points of the ease with which *B. pertussis* can be differentiated from *B. influenzæ*, the staff of the Danish State Serum Institute has been carrying on the bacteriological diagnosis of whooping-cough for several years for the benefit of general practitioners and others.

So far as we are aware no attempt has been made to corroborate or reject Bordet and Gengou's findings in this country. At all events, we have been unable to find any record of it. It is not clear from the published records whether Freeman's work relates entirely to observations made with cultures obtained from Bordet or refers also to strains isolated by himself (1909). In view of this state of affairs it seemed desirable to find how far the results obtained in Belgium and Denmark could be corroborated in this country; and in case they should be, to control the observations by determining the frequency with which this bacillus could be detected in the trachea and bronchi of children dying from various causes other than whooping-cough. The last type of observations does not appear to have been made and has obviously an important bearing on the significance of the detection of the organism in cases of the disease.

Technique of Culture.

The medium of culture used for the isolation of the organism was the one in use at Copenhagen slightly modified.

500 g. of sliced potato were boiled down in one litre of water with 40 c.cm. glycerine. The mass was filtered through a sieve, then through lint. To one part of the liquid thus obtained, three parts 0·6 per cent. sodium chloride solution were added. The mixture was rendered slightly alkaline (pH 7·5), 4 per cent. agar was then added, and the whole was then sterilised in the autoclave and tubed off in 7 c.cm. portions.

In preparing plates the tubes containing the potato-glycerine-agar extract were liquefied and allowed to stand in a water-bath at a temperature of 50° C., 3–5 c.cm. of sterile defibrinated rabbits' blood previously warmed in a water-bath to a temperature of 40° C. were then added to each, and the mixture poured into a sterile Petri dish and allowed to cool. Before pouring, the tube containing the blood and agar mixture was gently rotated by hand to bring about a thorough admixture of the contents, with the result that the plates appeared smooth, uniform, and of a bright red colour.

Method of Obtaining Sputum.—A sterile Petri dish in a suitable box was left overnight at the house of the patient and kept in a cold place till ready for use. The specimen of sputum was obtained early in the morning, so as to prevent any possible mixture of sputum with vomited food material. At the end of a paroxysm of coughing the child expectorated into the dish, which was again returned to the cold place until called for. Great emphasis was made on obtaining, if possible, thick, tenacious sputum expelled at the end of a paroxysm of coughing. On the average there was a period of two hours between the collecting of sputum at the house of the patient and its removal to the laboratory and inoculation on Bordet-Gengou medium.

Method of Making Cultures.—A portion of the thickest part of the expectoration was emulsified in 2–3 c.cm. sterile saline, and a very light inoculation of this was made by means of a platinum loop on to the Bordet-Gengou medium and spread over the whole surface by a slender glass rod, the terminal portion of which was bent at a right angle. Another portion of sputum was spread over the surface of a second plate without the preliminary dilution in saline. These two plates were then incubated at 37° C. and examined at the end of 24, 48, and 72 hours.

Bacteriological Findings.

After 72 hours' incubation small, raised, pearl-like colonies made their appearance. These colonies were so characteristic that it was possible when they were numerous to conclude from examination of the plate with a lens alone whether the Bordet-Gengou bacillus was present or not. Microscopic examination of these colonies showed small, ovoid, Gram-negative bacilli uniform in size and subcultures made on "chocolate agar" and Bordet's medium respectively fully confirmed Kristensen's observations. The *B. pertussis* when recently isolated gave little or no growth on "chocolate agar"—a medium particularly well adapted to the growth of *B. influenzæ*.

Kristensen's other differential point between the two organisms was not so clearly confirmed, for although it was found that *B. pertussis* after a preliminary incubation of three days remained alive at least four or five weeks in the ice-chest at 4° C., the behaviour of *B. influenzæ* strains was variable. Some certainly died much more rapidly; but three strains isolated during the 1929 Leeds epidemic were peculiarly resistant, although they did not survive as long as the *B. pertussis*.

A further differential point which has been observed independently in Japan is that the *B. pertussis* is one of the bacteria which give an exceptionally active catalase effect, whereas *B. influenzæ* gives a weak catalase effect.

The Japanese worker, Nishibe (1926), maintains that *B. pertussis* is further distinguished from *B. influenzæ* by giving an oxidase reaction with a dimethyl *p*-phenylene diamine and α-naphthol reagent. Ellingworth, McLeod and Gordon (1929), however, using tetramethyl *p*-phenylene diamine, which is more sensitive to oxidation than the dimethyl compound, observed that both *B. pertussis* and *B. influenzæ* oxidised this compound, although the former was more vigorous in its action.

All these facts go to prove that the bacillus of Bordet and Gengou must be recognised as a well-defined bacterial species distinct from the *B. influenzæ*.

Description of Cases.

The sputum from 17 patients suffering from whooping-cough was investigated and the Bordet-Gengou bacillus was successfully isolated in ten cases (see Table). With one exception, J. D., they were obtained from private medical practice. With the exception of patient H. P., the sputum was obtained in the post-catarrhal stage of the disease. In general medical practice it is very difficult to obtain early cases because treatment is usually sought when the characteristic paroxyms are already present. In Denmark, however, as the result of the establishment of a diagnostic station connected with the State Serum Institute at Copenhagen, the culture medium is sent out in aluminium Petri dishes on the demand of medical practitioners. In this way it is possible to examine a large number of specimens of sputum from patients affected with whooping-cough in all stages of the disease and also from suspected cases.

Table giving Summary of Results.

Patient	Sex and age.	Stage of whooping-cough.	Isolation of bacillus.	Patient.	Sex and age.	Stage of whooping-cough.	Isolation of bacillus.

y. = years; m. = months. P. = present. A. = absent.

A second small series of cases examined two years later gave the following results:—

Two cases examined in the week in which the whoop developed—both positive.

Two cases examined in the third week of the disease—both negative.

Two suspected cases which had not developed a whoop—one negative and one positive.

Post-mortem Observations.

Fifty children under 10 years of age dying from various causes were examined post mortem to determine the incidence, if any, of the Bordet-Gengou bacillus in the upper respiratory tract.

A similar technique was adopted throughout. The larynx, trachea, and lungs were removed intact. Surface sterilisation of each part was effected by means of a heated spatula. A sterile pipette was introduced below the surface and then the point pushed out laterally beyond the heated area; the material thus obtained was inoculated on to a "chocolate agar" plate and a plate of Bordet-Gengou medium, one plate of each medium being used for each part of the respiratory tract examined. The "chocolate agar" plates were examined at the end of 24–48 hours' incubation at 37° C. and the Bordet-Gengou plates at the end of 72 hours' incubation at 37° C. Any colonies of Gram-negative bacilli appearing on the "chocolate agar" plates were subcultured on to "chocolate agar" and ordinary agar and incubated for a further 24 hours. Gram-negative bacilli which grew freely on "chocolate" and failed to grown on ordinary agar were accepted as *B. influenzæ*. The result of these post-mortem investigations brought out the following facts: Percentage incidence of *B. pertussis* was nil, and that of *B. influenzæ* was 26 per cent.

Discussion.

These observations very definitely support the contention of Bordet and Gengou that the bacillus which they described is the cause of whooping-cough. The practical question whether the institution of a bacteriological diagnosis of whooping-cough would be of real value to the community should, in our opinion, be answered in the affirmative. For it seems to us that good use could be made of bacteriological diagnosis in the case of patients clinically doubtful, who might be a serious source of contagion—e.g., school-children. The slowness with which the colonies develop and therefore with which the results are available is a drawback, but it is possible that a method of overcoming this will be found.

Summary and Conclusions.

(1) The Bordet-Gengou bacillus was successfully isolated in 12 out of 21 cases of whooping-cough and in all of five cases examined within the first week of the disease.

(2) The organism required for its successful growth a Bordet-Gengou medium freshly prepared and on this medium after three days' incubation gave a highly characteristic small pearl-like colony. Microscopic examination of such colonies showed small, ovoid Gram-negative bacilli, uniform in size.

(3) The bacillus of Bordet and Gengou and *B. influenzæ* are two quite distinct bacterial species. The characters which distinguish them are the following:—

(1) *B. influenzæ* grows quickly, *B. pertussis* grows slowly.

(2) The appearances of the colonies on Bordet-Gengou medium are quite distinct; those of the *B. pertussis* being unlike those of any other bacterium that is commonly found in the sputum, and therefore the bacteriological diagnosis can frequently be made by inspection of the plates alone.

(3) *B. pertussis* can be preserved without subculture for periods of four to five weeks at least at temperatures of 10°–0° C.; whereas many strains of *B. influenzæ* are not easily kept without subculture for more than a fortnight under any conditions.

(4) The media most suitable for growth of *B. influenzæ*—heated blood agar, &c.—are quite unsuitable for the growth of recently isolated strains of *B. pertussis*.

(5) *B. pertussis* gives a very active catalase effect, *B. influenzæ* only gives a slight one.

(4) Secretions taken from the larynx, trachea, bronchi, and lungs of 50 children under 10 years of age dying from diseases other than whooping-cough and cultured on Bordet-Gengou media were not found to contain *B. pertussis*, although *B. influenzæ* was quite often detected in them.

(5) The bacteriological diagnosis of whooping-cough if generally adopted would probably be found to be easier and more exact than that of diphtheria and could be of practical service to the community.

We are indebted to Dr. Angus Campbell, of St. James's Hospital, Leeds, for help in obtaining some of the specimens of sputum examined, and to Prof. M. J. Stewart, Leeds, for access to the material from autopsies.

THE MANAGEMENT OF THE PSYCHOSES OF MIDDLE LIFE.*

BY IAN SKOTTOWE, M.B., CH.B. GLASG.,
D.P.M. LOND.,
SENIOR ASSISTANT MEDICAL OFFICER, CARDIFF CITY MENTAL HOSPITAL.

It has been recognised for many years by those in mental hospital practice that mental symptoms of a severe type frequently make their appearance in persons between the ages of 40 and 60 years. Recently however, with the growth of out-patient clinics for psychiatric cases, it has become clear that minor degrees of mental disturbance at this time of life may exist for many months before the patient is committed to a mental hospital, and that there were previously many such cases which never came under the care of psychiatrists at all. These cases appear to be a source of continued anxiety and distress to the relatives and the family physician, and their management is therefore of general interest.

It is the object of this contribution to indicate the methods of clinical approach to such cases as a whole, and to formulate criteria on which prognosis and management may be based. The title of this paper may have suggested the concept of a condition designated "involutional melancholia," and associated in some way with the menopause. Such a concept is misleading, for two reasons: in the first place, it is not in accordance with observed clinical fact. In many cases, the mental breakdown is separated from the menopause by a number of years on either side; and, furthermore, the symptoms of so-called involutional melancholia are often observed in men at the prime of life. In the second place, the name involutional melancholia implies the existence of a fixed symptomatology resultant upon some underlying fixed disease entity. The truth is that there are many clinical types of psychosis which may develop in the middle period of life. Some of them are associated with gross organic disease, some with functional physical changes, while in some it is not possible to demonstrate any physical change at all. The precipitating cause of a psychosis at this period of life may be one of many. It may be organic disease of the brain, or of the somatic field; it may be some environmental disaster, such as financial ruin; or it may be some inner difficulty of the patient's, about which he is unwilling to talk, or of which, even, he may be unaware, because such difficulties may have their true core in the subconscious.

The precipitating cause has but little effect on the symptomatology, for the symptoms are coloured and conditioned by the personality of the individual himself. This is concisely expressed by saying that when an individual breaks down mentally, he does so along the lines of his personality. The psychosis is, as it were, the distorted reflection of the individual as he was before he became ill. For this reason, the family physician can be of great help to the psychiatrist, and has, if he chooses to use it, a strong weapon of defence and prophylaxis against the psychoses. He knows the personalities of his patients. The psychiatrist knows what types of personality are liable to develop psychoses, and, further, of what nature these psychoses are likely to be.

Types of Psychoses Depend on Personality.

I will not dwell on personality descriptions, for their name is legion; but we may, I think, take two figures from literature for purposes of illustration. On the one hand, Cassius, with his lean and hungry look, and his propensity for thinking too much, typifies a personality which is prone to develop the malignant type of psychosis. At the other end of the scale is the fat, boisterous, jovial Falstaff, in whom a psychosis—if it occurred—would most probably be of the benign type. Between these extremes are infinite gradations; and it has been demonstrated clinically that the likelihood of recovery or otherwise corresponds closely to the position of the patient in the scale. Any attempt, therefore, to draw a composite clinical picture of the mental disorders of this period of life is unsatisfactory, because of their very nature. Clinical psychiatry is essentially the study of the individual patient. Psychotic symptoms, when they occur, are as variegated as the patients themselves; and this is true even of general paralysis. No disease is more protean in its early manifestations. Sometimes it is the patient, sometimes the relatives who seek advice; perhaps more commonly the latter. When this is so, there is a regrettable tendency on their part to embroil the medical man in some undignified subterfuge. One has heard, for example, of a psychiatrist being asked to call at the patient's house in the guise of the man who comes to wind the clocks. Cases are not unknown where the medical man has condoned such methods, by inviting the patient to come for a drive in his car and then depositing him within the precincts of a mental hospital, the true nature of which is not revealed. Such methods cannot be too strongly condemned; there is absolutely nothing to gain by them. Patients do not readily forget such deceitful practices, and they regard as an enemy not only their own physician, but possibly the profession as a whole, and thereby increase the difficulties of the case.

---

* A paper read before the Cardiff Medical Society, Jan. 8th, 1929.

Examination of the Patient.

From every point of view it is desirable that the medical man should be open and frank. Let him tell the patient that his relatives believe him to be ill, and that he has come, in the capacity of a physician, to examine him. If the patient is truly psychotic, nothing that he may do will hide his symptoms from one trained to elucidate them; while, if he is not psychotic, there is no harm done.

A routine physical examination is, of course, essential; but it is generally desirable, if the case is not obviously one of gross physical illness, to make the mental examination first. There is only one satisfactory way to do this. It is to write down what the patient actually says and does, and the setting in which he says and does it. These are matters of fact, anything else is a matter of opinion. To say that a person is deluded, hallucinated, confused or irrational is merely to express the opinion of the examiner; but, if one writes down, for example, the question, "Do you seem to hear voices?" and the reply, "Yes, like electricity in the head"; or the question, "What year is this?" and the reply, "1899," when it is actually 1929, then one has a permanent record of fact, which may become incontrovertible documentary evidence should legal complications arise later.

The special fields we want to investigate in the mental examination are three in number: (1) The emotional state or mood of the patient. (2) What the patient is thinking about; that is, the content of thought or mental trend. (3) The state of his purely intellectual functions. By "intellectual functions" one means memory, ability to retain simple facts, ability to do calculations, and to orientate one's self in time and place.

1. *The mood.*—The indications of the state of the mood are the patient's facial expression, gesture and attitude, and his statement of how his feelings and spirits are. A psychosis may manifest itself in three ways in this field. They are as follows:—

(*a*) By exaggeration of the emotional state, with or without apparent cause. For example, a patient becoming profoundly depressed after some trivial financial loss, or for no apparent reason at all.

(*b*) By the presence of apathy or a mood which is not in harmony with the patient's thoughts. The commonest example of this is where the patient states that he is being annoyed or interfered with in some way and yet does not, in spite of superficial protestations, show any real resentment thereto.

(*c*) By instability of the mood—where, in the course of a few minutes, the patient will laugh or weep without apparent cause, and will change from laughter to tears very quickly.

The state of the patient's mood gives us some clue to the questions we should ask in the investigation of the next field, viz.:—

2. *The content of thought.*—For example: "Why are you unhappy?" "What do you think is the cause of your depression?" "What are you afraid of?" When investigating the content of thought, we must find out whether the patient's experiences are real or imaginary, and whether his personal beliefs are generally accepted as correct or erroneous. In other words, are his thoughts made up in part of hallucinations and delusions? This often involves the use of leading questions.

3. *Investigation of the intellectual functions of memory, orientation and reasoning.*—The proper mode of approach is to ask the patient about chronological events in his life, beginning with the time he left school following it through such events as employment, marriage, children, deaths of parents, &c., and public events, such as the war and the general strike. Make him give as many dates as possible; and when he tries to gloss over some period, go over it in particular detail, afterwards comparing notes with the relatives. In this way, instances of amnesia or confabulation become apparent. Be particularly on the look-out for incongruities, instanced by a patient who said she was employed as a nurse in 1921, and after that went to make munitions.

Orientation is simply tested by asking the patient if his head feels clear, if he knows the date, where he is, and identifies those about him correctly.

Reasoning is most readily determined by asking the patient to do a few simple calculations.

Having completed the mental examination in this way, we find in a psychotic case that, although there may be changes in all these fields (namely, the mood *the content of thought and the intellectual function*), the change in one of them usually overshadows the others and dominates the clinical picture. Thus, we have three broad types of psychoses: (1) Those in which some profound emotional disturbance dominates the picture. We call these the affective disorders. (2) Those where there are hallucinations or delusions, without much emotional change. These are the paranoid psychoses. (3) Psychoses characterised by impairment of the intellectual functions—the organic psychoses.

The Affective Disorders.

In the affective disorders, the prognosis is generally good. The more acute the onset, and the more dramatic the symptoms, the sooner will the patient recover. Acute cases recover in from three to six months, while cases of gradual onset and less profound change take from five to seven years to run their course. If, in addition to the emotional change, such patients have definite delusions of unworthiness, sinfulness, or fear of torture, then certification must be resorted to. Many cases of affective disorders, however, do not present definite delusions, but have mental trends of a self-depreciatory kind; they feel "no good," or wretched; the difference is only one of degree. In that event, the management of the case depends on the financial status of the patient. If he can afford it, he should go to a registered hospital as a voluntary patient; and the sooner he is in hospital the better. He will be in the hands of people who understand his illness; cared for by nurses trained to deal with such cases; in a place properly equipped for the treatment, by physical, psychological and occupational means, of the illness from which he suffers. There should be no hedging about going to hospital. The situation must be faced and dealt with. It is the duty of the profession to kill the old, fatalistic attitude to mental hospitals. The patient and the relatives should be made clearly to understand that the sooner the patient is in hospital the better his chance of early recovery. One hears all sorts of arguments about the unfortunate effect upon the patient of placing him among a lot of "lunatics." There are two answers to this: one is that these cases are often worse at home than in hospital; and the other is that one has never seen or heard of a patient being definitely, unfavourably affected by being in an environment of people suffering from a kind of illness similar to his own. Moreover, any psychiatrist can tell of innumerable cases which have become certifiable and have run a protracted course, when voluntary admission to hospital in the early stages would have resulted in recovery long since.

If the patient is in straitened financial circumstances he cannot go as a voluntary patient to the ordinary rate-aided hospital in England. Such patients must be treated at home, preferably with regular visits to some out-patient clinic for psychiatric cases. It is important that the sleep and weight be recorded carefully. To secure sleep and diminish agitation, veronal in 5 or 10 grain doses, thrice daily, is effective. It should not be continued too long; and, after a week or so, bromide in 30 grain doses, t.i.d., may be substituted. The gospel of fatness has stood the test of time; and by means of gastric tonics, cod liver oil, arsenic and iron, the weight should be built up. Drug therapy, however, only helps us in the alleviation of symptoms. The psychosis is a distortion of the individual as a whole. We all know how easily habits are developed. Now, psychotic behaviour and modes of thinking are apt to become a habit with the patient, and so set up a vicious circle. We should endeavour, therefore, to make the patient develop habits of ordinary behaviour and ordinary thought.

The two great means of doing this are occupation and persuasion. Make the patient do something—no matter how simple, be it sewing, reading, painting, carpentry; anything so long as he is occupied, preferably with some creative work; something he can look at and realise that he has done himself. In this way, nor only do we tend to keep the patient's thoughts off himself, but we restore his broken self-regard and feeling of usefulness. Occupation is not suitable for the more acute forms of these psychoses. It is a mistake to force the pace too much, but firmness is essential; and we must be guided by the condition of the patient. In any case, a patient who is suitable for home treatment is, in all probability, suitable for occupational therapy. Persuasion is more logical than crude suggestion, and less coldly intellectual than argument. It means not only pointing out to the patient that he is ill, that he must regard his distress as a symptom of illness, and that he will get well; but we must stimulate him; point out his duty to others; fill him with hope, and reason out his little troubles one by one as they arise. Make him feel that we understand him, and that we want to help him; give him some model on which to arrange his life; give him a daily programme, and let him take a pride in keeping to it; for discipline is of great help in restoring a feeling of self-regard in patients suffering from these psychoses. Finally, the possibility of a suicidal attempt in states of depression must never be forgotten; and the relatives should be warned not to let the patient be alone.

The Paranoid Psychoses.

The next group, the paranoid psychoses, with their lack of emotional disturbance, but profound change in the content of thought, are extremely unfavourable cases, usually of long and insidious onset, and eventually ending in a fixed delusional system. Early certification is desirable, not only from the point of view of the patient, but also from the social point of view. Many of these patients get themselves into difficulties with neighbours, the police and other public bodies, because they think they are being watched or persecuted, or because they believe themselves to have some great reformatory mission in life. As soon as one can write down some odd belief of the patient's, which, in non-technical terms, clearly demonstrates his lack of insight into his condition, he should be certified. Because of this lack of insight it is usually impossible to get the patient to go voluntarily to hospital. On the subject of certification it may be said, in passing, that the writer of the certificate, no matter how often he has written one, should bear in mind two things: (1) to read carefully and obey to the letter the marginal notes and instructions on the certificate form; (2) to put down only matters of fact—not opinion—and to avoid technical terms, remembering that his certificate has to convince a layman of the patient's unfitness to manage himself or his affairs.

The Organic Psychoses.

The last group are the organic psychoses, characterised by intellectual impairment. Now, intellectual impairment is an almost infallible criterion of actual disease, injury or poisoning of the brain. We may, therefore, usefully recognise two sub-divisions of this group. They are: (*a*) psychoses with organic brain disease. (*b*) Psychoses with other somatic disease. Both of these sub-divisions call for special physical investigation. We should, therefore, get the patient into a nursing home or general hospital—according to his financial status—in order to do the following: lumbar puncture; fundus oculi examination; blood pressure; microscopical urine examination and kidney-function tests; complete blood count. Our lumbar puncture will settle the question of general paralysis, cerebral syphilis and a few other organic nervous diseases. If we find evidence of general paralysis, then malarial treatment should be given if the cardiovascular condition is satisfactory. Many cases are sufficiently well mentally to permit of this being done in a general hospital. If syphilis can be ruled out, we should seek carefully for evidence of arteriosclerosis in the urine, blood pressure and fundus oculi. Many arteriosclerotic patients have exacerbations of mental symptoms from time to time, and sometimes, in such exacerbations, they are certified. Unless excitement is extreme, this is not a justifiable course to take without first trying the effects of free purgation, by saline purgatives, diminution of protein intake and exhibition of iodides. It is surprising how many patients, apparently with arteriosclerosis, show a great mental improvement under such treatment. If syphilis and arteriosclerosis can both be ruled out, alcohol should next be considered; and here the history should help us. The prognosis for acute attacks in alcoholic psychoses is very good, and most of them may be treated at home; but, of course, future attacks are extremely likely to occur, unless the patient is willing to go to hospital for a prolonged period. Lastly, if all these conditions can be ruled out, we must seek some gross infection. A leucocyte count should help us; and, in addition to the usual places of focal infection, the urine should be examined bacteriologically, because a *B. coli* infection of the urinary tract is not rarely the focus, and one can recall at least one miraculous cure of a psychosis by the exhibition of large doses of bicarbonate of soda.

Summary.

Three types of psychosis are seen in middle life. They are: (1) The affective disorders, where exaggeration of the emotional state is the cardinal symptom. (2) The paranoid psychoses, characterised by delusions and hallucinations, without much emotional change. (3) The organic psychoses, characterised by intellectual impairment.

In the affective disorders, the prognosis is good in direct proportion to the acuteness of the symptoms. Certification, voluntary admission and home-treatment are appropriate to varying degrees of the disorder. The paranoid psychoses are unfavourable, and call for certification. The organic psychoses may be associated with disease of the brain, or with other somatic disease. The presence of syphilis, arteriosclerosis, alcohol or gross infection should be determined by extended physical examination. Many cases in this group—particularly those associated with arteriosclerosis, alcohol and gross infections—are capable of being satisfactorily treated under home conditions.

A brief survey of a large clinical field is necessarily didactic. There are exceptions to the rules I have formulated, but I have endeavoured to present a large field as a whole rather than to side-track the issue by a wealth of minute detail.

Clinical and Laboratory Notes.

THE MEINICKE MICRO-REACTION.

BY G. DE M. RUDOLF, M.R.C.S. ENG., D.P.H., D.P.M.,
SENIOR ASSISTANT MEDICAL OFFICER, LEAVESDEN MENTAL HOSPITAL; LATE ASSISTANT MEDICAL OFFICER, CLAYBURY MENTAL HOSPITAL.

MANY tests have been devised with the object of obtaining some simple reaction for the detection of syphilis, but perhaps none is so simple as Meinicke's micro-reaction. The blood may be obtained from a prick, and the apparatus consists of platinum loops, microscope slides and cover-slips, a microscope and an antigen which is stable and can be bought ready for use. Although the reading of the test requires some experience, the technique is simplicity itself. Full details of the technique are sent with the antigen by Meinicke but will be found in English in a paper by Prentice in this journal.[1]

At the suggestion of Dr. G. F. Barham, medical superintendent of Claybury Mental Hospital, a number of sera have been examined by this test. The Wassermann reactions (W.R.) were performed on the same sera at the central laboratory of the London County Mental Hospitals Service by Mr. F. Partner under the direction of Dr. F. L. Golla, the director.

The accompanying table shows the results obtained together with those of some other workers. Of a total of 2750 specimens examined 89·4 per cent. agreed with the results of the W.R. The percentage of agreements varied in the different series from 74·4 (Claybury) to 93·3 (Prentice[1]). When it is recalled that all the workers used practically identical techniques for the Meinicke micro-reaction, but that different techniques would be employed for the W.R., the high percentage of 89·4 for the total series is striking. Rucker and Whitby[2] carried out two series of tests. Column 1 under their names in the table shows the results obtained with an antigen prepared by these authors similar to Meinicke's own extract but without previous extraction of the horse-heart muscle with ether, whereas Column 2 shows the results obtained by these workers when Meinicke's own extract was used. The agreements were 88·5 per cent. in Column 1 but 93 per cent. in Column 2.

—	Claybury.	Saunders.	Rucker and Whitby.		Kovacs.	Prentice.	Total.
			I.	II.			
W + M +	29	111	57	149	461	400	2461 (89·3 %)
W — M —	302	799	151				
W ? M ?	2	—	—				
W.A. M —	—	9	—	11	—	29	103 (3·7 %)
W.A. M +	—	13	—		—		
W ? M +	—	8	—		—		
W ? M —	4	7	—		—		
W + M ?	2	5	—		—		
W — M ?	42	13	—		—		
W + M —	22	16	15		11		186 (6·8 %)
W — M +	43	19	12		48		

W = Wassermann reaction; M = Meinicke micro-reaction.
A = Anticomplementary.
+ = Positive. — = Negative.
? = Doubtfully positive or doubtfully negative.

Rucker and Whitby point out that the chief difficulties in the reading of the tests occur in the sera from treated cases. Kovacs[3] believes that the test is definitely reliable in untreated cases and the statement has been made that the reaction is more sensitive than the W.R. Of 19 sera examined by Saunders[4] and giving negative W.R. with positive Meinicke micro-reactions, 11 came from patients who had had syphilis or had shown positive W.R. previously. Of 16 sera tested by the same author and giving positive W.R. with negative Meinicke micro-reactions 11 came from cases of general paralysis who had been given a course of two years' treatment with tryparsamide and salvarsan continuing up to two weeks before the tests.

In conclusion my thanks are due to Mr. F. C. Radley, laboratory assistant, Claybury Mental Hospital, for assistance in the work, and to Dr. Barham and Dr. Golla for permission to publish the results.

A NEW METHOD OF MAKING A PERMANENT SUPRAPUBIC OPENING.

BY W. CUTHBERT MORTON, C.B.E., M.D. EDIN.,
HONORARY DEMONSTRATOR IN ANATOMY IN THE UNIVERSITY OF LEEDS.

PROSTATECTOMY leaves nothing to be desired when it succeeds; too often it either cannot be done or else fails. If the operation is performed the general practitioner must be prepared to lose a life otherwise good; if it is not performed, he may have to take part in the humiliating ritual of a painful catheterism or to stand by for a year while nature lines a suprapubic opening.

Two most unfortunate cases led me to wonder whether there might not be scope for a permanent opening lined by a tubular graft of the prepuce. At a first operation the distal margin of the protracted prepuce would be incised circularly and the inner layer inserted through a freshly made suprapubic opening so that its distal margin could be sutured around the incision in the bladder wall, after which the distal margin of the outer layer would be sutured around the cutaneous incision no raw surface being left exposed. At a second operation, when the graft should have taken, circumcision would free it and its cut edges would be joined by suture. Three or four weeks should be enough for obtaining the permanent opening, and contraction of the linea alba might enable the urine to be held for some hours. The catheter, should it prove necessary, would cause little pain since the nerves to the graft would have been cut by the circumcision.

FIG. 1.

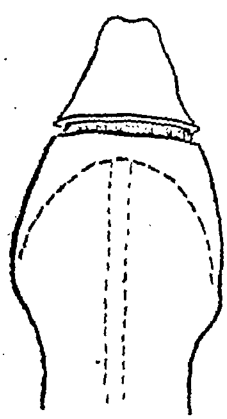

FIG. 2.

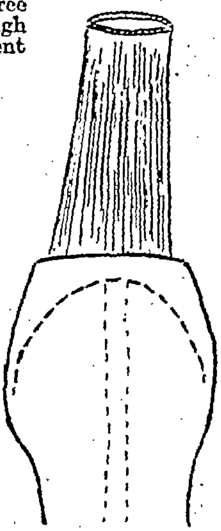
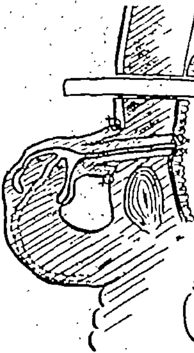


Diagrams showing incision in outer skin of the prepuce.

Description of the Operation.

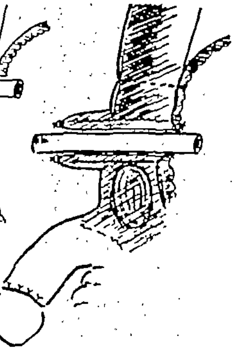
Mr. L. R. Braithwaite, with whom the question was discussed, at once arranged to try the method on the first suitable case. I am indebted to him for the following description of the operation and above all for the interest which he has taken in the method and for the successful issue which means so much to my patient.

FIG. 3.



Medial section.

FIG. 4.



Oblique section.

"The patient was a man 65 years of age, with a urethral stricture of such a kind that it was impossible to pass the finest bougie through. A radiogram of the injected track through the stricture showed it to be not only an exceedingly narrow one but also one of the 'corkscrew' variety, too extensive in its *length for successful excision or incision. Cystitis of* the foulest type had developed and the condition of the patient was so low that a suprapubic drainage had become essential two months before the new operation was attempted. As a result of drainage and lavage the degree of cystitis was much diminished.

"Provision must be made for temporary bladder drainage during the fixation of the pedicle graft. In this case the usual incision above and very close to the symphysis pubis had been already made and a self-retaining catheter was acting as a 'permanent' bladder drain.

"The catheter having been removed, the whole of the track from skin to bladder wall was excised, the wound being lengthened at the same time so that it was about two inches long. With a finger through the wound an incision was made through the abdominal wall into the bladder, one and a half inches above the level of the upper edge of the lower incision. Into this upper wound the temporary bladder drain was placed (Fig. 3). The prepuce, having been drawn out fairly tightly, was encircled by an incision about half-way along its length, dividing the outer skin of the prepuce only (Fig. 1). The distal cuff of skin was then drawn forwards (inverted) (Fig. 2), making a long tube, lined by skin on its inner side. This tube was to be made to lie in the substance of the abdominal wall from skin to mucous membrane of bladder. The elongated cuff of prepuce was now drawn through the prepared track and fixed by six fine catgut stitches accurately to the bladder edge (Fig. 3). The old abdominal wound was now stitched closely up to the preputial tube and that portion of proximal preputial outer skin left covering the glans was easily stitched to the abdominal skin at the margins of the old suprapubic wound, drawing the glans fully up to the abdomen.

"Some œdema of the prepuce developed outside the abdominal wall, but no evidence of impending gangrene. After 14 days a circumcision was performed and the penis allowed to fall back (Fig. 4). In three days the tube in the upper suprapubic wound was removed and another smaller tube placed along the new track now fully lined by preputial skin. In 10 days the upper suprapubic wound was completely closed by natural means. For three or four weeks the preputial graft remained swollen and œdematous, after that time it became normal and has shown very little, if any, signs of contraction. The skin-lined track has certainly become much narrower but no more than is necessary to keep it watertight. The result has been very gratifying. It is of interest to quote from the patient's letter to Dr. Morton, dated May 7th, 1929 :—

> "I find it only necessary now to pass water about once in five or six hours—never less than four hours—using a short silver or plated catheter, No. 8, which of course means getting a good night's rest. No leakage occurs unless, through force of circumstances, I am obliged to disregard the warning desire to relieve the bladder, and then a small quantity, say about a tablespoonful, is passed through the urethra only. Believe me, my best thanks will always be due to yourself as the inventor of the operation, and to the surgeon who performed it at the infirmary, and afterwards directed its treatment.

"Seen a few weeks ago the patient was wearing no dressing of any kind over the new opening, it was perfectly dry, and showed no sign of irritation. The new track was free from all pain or tenderness and the introduction of the short straight tube was accomplished with the utmost ease and celerity. There can be no doubt whatever that the operation has its use though obviously limited by reason both of sex and sect."

HEPATIC AMŒBIASIS SIMULATING CHOLECYSTITIS.

DRAINAGE OF ABSCESS BY CHOLECYSTOSTOMY: RECOVERY.

By IAN MACDONALD, M.D. EDIN.

IN a valuable paper on hepatic amœbiasis, based on a surgical experience of 252 cases, *Lacaze* and Melnotte[1] emphasise the difficulties of its differential diagnosis. Confusion with cholecystitis and appendicitis is apparently not infrequent when the attacks are periodic and associated with rigidity of the right side. In the case reported here, the preoperative diagnosis was cholecystitis and appendicitis, though the possibility of an amœbic abscess was not forgotten. Conservation of the gall-bladder fortunately allowed satisfactory drainage of the abscess.

The patient, a military man aged 39, was admitted suffering from acute pain in the right hypochondrium and right side down to the iliac fossa, with irregular fever, which had reached 103° F., accompanied by sweating and chills. Pain had been so severe that morphia had been necessary night and morning for a week. He had had one previous attack of dysentery 18 years before in Morocco. He had suffered in ten years from three similar attacks of pain, which had been diagnosed as biliary lithiasis. During the last eight months the attacks had been more frequent, but in all the intervals the patient had been quite well. He was a thin, sallow-looking man with a subicteric tint. Palpation elicited great pain down the right side as far as McBurney's point. Palpation for abscess laterally and posteriorly between the ribs was quite negative. The patient insisted on the severity of his subcostal and right-sided pain. Percussion of the liver seemed to show enlargement, but even light percussion was extremely painful and the right rectus muscle was continuously contracted. There were no urinary symptoms nor antecedent dyspepsia. In the attacks the pain radiated upwards towards the chest, shoulder, and back. On admission more morphia had to be given as the pain was so severe, but the pulse-rate was only 80.

Operation.—Under ether anæsthesia the abdomen was opened by a long Kocher incision with a short vertical prolongation upwards in the middle line. A large liver was exposed, and on lifting its anterior edge a very thin-walled, dilated gall-bladder prolapsed into the wound. The gall-bladder was about four times its normal size and had the colon fixed along its under surface. This adhesion, however, proved to be a fine flattish fold ; on cutting it the neck of the gall-bladder was easily reached. Palpation of the ducts revealed no stones and it was difficult to account for the obvious stasis in the gall-bladder. Palpation of the upper and lower surfaces of the liver showed no definite abscess, but needling was not employed. The gall-bladder was next opened after emptying it of foul-smelling, black bile; it contained no calculi. In view of the poor condition of the patient, the obviously enlarged liver, and the uncertainty of the nature of the cholecystitis, simple cholecystostomy was selected as least likely to cause trauma to the liver. A piece of omentum was fixed between the raw surfaces of the gall-bladder and colon and a large Pezzer catheter was placed in the gall-bladder. The appendix was then removed, without invagination of its stump, through a small McBurney incision. It was obviously diseased, contained two stercoliths, and was acutely kinked about the centre.

---

[1] Lacaze, H., and Melnotte, P.: Rév. de Chir., 1935, lxvi., No. 10.

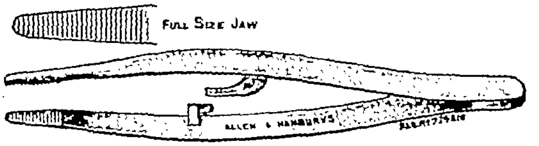
The immediate results of the operation were excellent. The acute crises of pain at once ceased and a large amount of black, fœtid bile was discharged by the tube. On the third day, however, the bile became turbid, and slimy pus, with pieces of necrotic material mixed with small blood-clots, was evacuated by the tube. Though a laboratory report of the pus and fæces was negative for amœbiasis, the clinical diagnosis was now clear. Four centigrammes of emetine were administered night and morning for twelve days, and 60 cg. of stovarsol were given daily by the mouth. The purulent discharge rapidly lessened and in ten days the bile was practically clear of pus. The tube was removed on the nineteenth day and the patient left, with the wound soundly healed, one month after admission, with instructions to continue the emetine treatment during a fortnight in each month. Three months later he was in excellent health.

Huelva, Spain.

New Inventions.

AN IMPROVED ARTERY FORCEPS.

THIS is a modified dissecting forceps having jaws similar to the standard Spencer Wells's artery forceps, and is fitted with an improved spring catch which locks, when compressed, and unlocks with further compression. The forceps can be readily manipulated in the hand, there being no delay in inserting digits into rings as in ordinary forceps and they can be gently and easily removed with either hand, even by an unpractised assistant.

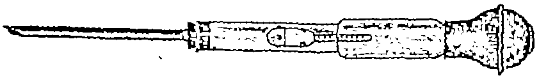


These forceps have been made to my special design by Messrs. Allen and Hanburys, Ltd., Wigmore-street, London, W.

HUGH DONOVAN, M.B., Ch.B. Birm., F.R.C.S. Eng. and Edin.

A LABOUR SAVER IN THE EXAMINATION OF URINE.

Disliking the task of filling test-tubes direct from a pot and having to wash up a greater number of pieces than necessary, I have had a battery hydrometer adapted for urine. This instrument, shown in the illustration, will pick up a specimen from any kind of vessel, give the specific gravity, and fill a test-tube without spill or mess. The usual cleansing of pipette urinometer and trial jar is reduced to the one simple operation of drawing in clean water and squirting it out again.



The hydrometer may be obtained from Messrs. A. Charles King, Ltd., 34, Devonshire-street, London, W.

G. RAMSEY PHILLIPS, M.R.C.S.

ROYAL SANITARY INSTITUTE.

CONGRESS AT SHEFFIELD, JULY 13TH–20TH, 1929.

THE fortieth annual congress of the Institute was in some ways the most successful of the long series. Its keynote was coöperation. One notable event was that the congress set its seal on the inclusion of mental hygiene within the purview of public health. The delegates who visited Sheffield for the first time and had heard it described as "a bit of hell dumped down in heaven" would not wonder at the beauty of its environment, made accessible to them by many excursions and much hospitality, but they may have been agreeably surprised at the evidences everywhere of a progressive municipality.

AMENITIES OF CIVIC LIFE.

Mr. W. J. HADFIELD, the city surveyor, described the great increase in the number of asphalt roads. In 1917 there were 1316 super. yards and in 1929 just on a million. Mr. Hadfield claimed for them greater cleanliness and silence and also durability and economy in construction, and received many congratulations from his engineering colleagues. Mr. WM. TERRY (general manager) described the excellent municipal water-supply, and incidentally put in a plea for "the effective control of both surface and underground waters by a properly constituted authority entrusted with the duty of husbanding the national sources of supply and allocating them to the best advantage."

Councillor W. ASBURY, chairman of the Sheffield Health Committee and of the Sheffield and Rotherham Joint Smoke Abatement Committee, presided over a good discussion on smoke abatement, and advocated that the whole country should be mapped out into regional areas, each controlled by a joint committee with statutory power. *When this had been done a* central committee could be formed to consider the best method of tackling the problem on a national scale and to conduct research work and arrive at a uniform standard. The Rogers Field medal, the principal award offered by the Institute, was won by Low Temperature Carbonisation, Ltd., for an exhibit of Coalite Radiant Smokeless Fuel. This medal has only been awarded twice previously during the past 25 years.

During the discussion Mr. H. G. CLINCH (chief sanitary inspector, West Ham) referred to a similar coke produced by the Gas Light and Coke Company and sold under the name of Gloco. The delegates who saw the Coalite fire burning in the exhibition must have agreed with Mr. Clinch that when such a smokeless fuel is available generally at a reasonable price no hardship will arise from the prohibition of the use of raw coal for domestic purposes and the domestic smoke problem will have been solved.

Most of the delegates utilised the efficient municipal tramway and motor-bus service, many visited the sewage disposal works to see a good illustration of the bio-aeration system, and the new municipal abattoirs received unqualified praise.

The discussions held and the papers read at the 12 sections and conferences were very numerous, and it is only possible to refer to a few of them in detail.

MENTAL HYGIENE.

The first session of this discussion was devoted to the interests of the child and the second was from the point of view of the adult. Prof. ARTHUR HALL, who presided, referred to the pioneer work of Wycliffe Wilson, who had always attached great importance to the moral and mental effect of the "scattered homes" for poor-law children, for the origination of which he would always be gratefully remembered. He went on to refer to the out-patient department of the South Yorkshire Mental Hospital, which was endeavouring to get hold of early cases, but also needed beds for short-stay cases.

The Child.

DR. RALPH H. CROWLEY opened the discussion on mental hygiene for the child. This was, he said, an extraordinarily difficult undertaking. The gaps in our knowledge as to the prevention of undesirable and *harmful mental states should warn us against undue* optimism. We needed to learn the significance of behaviour problems in general and for any particular child. Only after much patient work should we learn what abnormalities in behaviour were significant, at *what age and in what combinations; and what are* probably the forerunners of delinquency, of crime, of nervous disorder, of insanity. A public organisation would be needed to secure the team work of psychiatrist, psychologist, welfare worker, nurse, teacher, parent, and child. The retarded children, who formed 10 per cent. of the school population, would claim special attention. A child who was a failure at school early lost heart and made a bad start for his adolescent life. The specially trained staff was the crux of the matter. Hitherto we had devoted ourselves too exclusively to the manifestations of the mind through the intellect and had neglected the manifestations of the mind through behaviour, and there was in consequence much undeveloped creative activity. Men and women were not making their full contribution to the common life. Mental hygiene must take its place as part of the public health service. The resources of the community must be brought to the service of the individual at each stage of his life so as to give him the chance of the fullest and highest development.

Dr. WM. MOODIE (Child Guidance Council Clinic) referred to the anxieties of parenthood, which could be greatly minimised if the parent were warned beforehand and given confidence to face potential troubles. "Parent teacher" associations, pre-natal clinics, and nursery schools could do excellent work. For the effective working of child guidance clinics it was essential to have specially trained social workers, because parents and relatives could not accurately and impartially describe their problems, which had an effect on the child.

Dr. LETITIA FAIRFIELD referred to the large amount of obscure talk about psychology. At present they only dealt with end-results; yet naughtiness was more important, though perhaps less interesting than *criminology. They must spread the* knowledge of psychology to all who had to care for children. Consultant clinics for difficult cases were needed. The period under five years was the most important, but it would be ridiculous to have child guidance clinics *for that age, and they must work through the* mothers and the teachers, through maternity and child welfare centres and nursery schools. There was not enough character training in the maternity and child welfare centres and there were not enough "McMillan" nursery schools. At the age-period from 5 to 16 the child only spent a fraction of his life at school. In America they had endeavoured to fill this gap by appointing home-visiting teachers. An out-patient mental clinic could not work successfully without expert home visitors. In Canada the work of ascertaining mental deficiency was being extended to conduct troubles and problems, and the school nurse was specially trained in mental hygiene. Child guidance clinics would be a great disappointment if they were not conducted by real experts.

Dr. EVELYN FOX (Hon. Secretary, Child Guidance Council) stressed the importance of social workers being trained in this dangerous and difficult work. The medical profession did not yet appreciate what was meant by a mental hygiene social worker. They must create a demand for such workers, who would be the passers-on of the skilled advice of the psychiatrist to the family.

Dr. G. A. AUDEN (school medical officer, Birmingham) pointed out that nursery schools could not put right home maladjustments. The parents of only children needed instruction that their child had to live its own life and must learn to stand alone. The sense of inferiority in school work was often the beginning of trouble.

Dr. A. E. NAISH agreed that the mental upbringing of children was neglected, but said we must go slowly. Years of study were needed and mental hygiene would be an art and not a science for a long time. At early ages we must work through the mother. Unless we *had good instruction to give it was better to give* none at all. The child must be given its own reasons for controlling its emotions. Councillor OLDERSHAW (chairman of the Health Committee, Maidenhead) said that in his experience as a crammer he had to *deal with many* "*only child*" and "step-mother" failures. He sounded a note of warning as to the trouble caused by bad psycho-analysis.

Dr. HARVEY SUTTON (New South Wales) said that it would be necessary for the child guidance team to *keep an all-round view and not neglect the physical* side. For example, deafness might lead to incorrigibility. The school medical officer needed some training in psychiatric work. Dr. COLSTON WILLIAMS (Glamorganshire) asked how we were to make a beginning.

The Adult.

Dr. E. MAPOTHER (superintendent, Maudsley Hospital) said that in a wide sense the aim of mental hygiene was the abolition of madness, badness, and sadness. He found that mental disorders only had an organic origin in 25 per cent. of the total, and that there was a distinct decline in the cases caused by alcoholism and syphilis. As regards functional mental disorder there was no true prophylaxis as yet, only the possibility of early treatment. It was impossible to shelter the potential neurotic from injurious experience, and many of the world's greatest achievements had been made by the unstable facing the risks of a breakdown. Even from the neurotic's own standpoint it paid better to live dangerously than to play pawky. Dreary second-rate lives were a more frequent cause of mental disorder than overwork or disaster and the infliction of security through renunciation was the worst of services except on real proof of necessity. The pivot of the system of early *treatment was the psychopathic clinic, and at present* the only English example was the Maudsley Hospital. In its first six years this hospital treated 3000 in-patients and 7000 out-patients. None of these patients had ever been certified and less than 1 in 8 had left *against advice—just because they were free to do so.*

Dr. W. VINCENT (medical superintendent, Wadsley) said that every public hospital should have its special department for incipient mental disease. There should be beds available as well as an out-patient department, and specially trained home visitors on the staff. Dr. R. W. GILMOUR (lecturer in psychiatry, Middlesex Hospital) held a brief for the minor mental and functional nervous disorders. The alienist was more interested in the individual and the physician or hygienist in the case, but they were all coming together gradually. The wrong mental interpretation of sensations was a great source of misery and was not cured by saying "Don't be silly!" Early mental symptoms needed treatment just as much as early symptoms of physical disease. Mental defect due to birth injury was not transmissible to the children. Much was said about the inferiority complex, but he considered the superiority delusion just as important.

Mrs. C. B. S. HODSON (the Eugenic Society) said there was a distressing increase in mental disorder in *many countries. She showed charts to illustrate the* increase in this country from 1850 to 1913, and the fact that the increase was chiefly among pauper lunatics. She thought the eugenist should be linked up in the team and that the time would be ripe for a real consideration of sterilisation at their next meeting. The eugenists did not aim at the production of supermen, but rather wished to eliminate the non-adaptables, who could not afford to live dangerously.

Dr. G. MOULD (physician, mental diseases, Royal Hospital, Sheffield) spoke from 30 years' experience of a mental clinic at a general hospital of the value of such clinics.

Dr. A. GURNEY YATES (Sheffield) said the time was ripe for dealing with early cases by an organised scheme. The Royal Infirmary had just started a *mental clinic. In the treatment of early cases they* would be able to study causation.

Prof. **W. H. FROST** (Johns Hopkins University, U.S.A.) was much impressed with the fact that two sessions had been devoted to mental hygiene and that every speaker had made concrete proposals.

Councillor **WILLIAMS** (Sheffield) said we must have mental hospitals for mental breakdowns free from any slur or stigma. Other speakers dwelt on the bad effect of unemployment and a hopeless outlook, and that the public must be educated in the need for and use of mental hospitals.

Dr. **MAPOTHER**, in reply to a question as to the increase in mental disorders, pointed out that it was difficult to make a fair comparison with former years because the standards for discharge were now higher and the death-rate among the patients was lower.

LOCAL GOVERNMENT ACT, 1929.

Dr. **J. J. BUCHAN** (M.O.H., Bradford), in his presidential address to the Conference of Medical Officers of Health, which met on July 18th, dealt with the care of the sick under this new Act. He pointed out that Section 5, which exhorted councils to a certain course of action, was at present permissive in character. It enabled a council to declare in its scheme under the Act that any medical assistance shall not be of the nature of poor relief, but shall be provided under the Public Health Act of 1875. The mere change of ownership of hospitals from guardians to councils was of no moment, unless accompanied by detailed changes in working. Even the best poor-law infirmaries were seldom quite free from remnants of the old deterrent principle. Admission to the new hospitals must be made easy for persons that needed hospital treatment. The recovery of expenses must not be made in such a way as to deter sick persons from seeking hospital treatment. Hospital provision was an exceedingly onerous duty, and they must get what help they could from voluntary bodies.

Dr. **W. ALLEN DALEY** (M.O.H., Hull) detailed the advantages which would accrue to the maternity and child welfare and school medical services if the Act were properly worked. He referred to the "penal" clause, Section 104, which enabled the Minister to reduce the grant payable to any authority if satisfied that such authority had failed to achieve a reasonable standard of efficiency, and also gave a statutory right to voluntary bodies to make representations to the Minister if services in their area appeared to be neglected. Grants which had formerly been made direct to voluntary associations would now be made through the local authorities. In the case of rescue homes it was properly thought desirable to remove an unmarried expectant mother to a distance from her old surroundings. Such rescue homes should not lose their grant because they catered for persons from another district. The health committees ought to become the new public assistance committees. The health committees would run all institutions and have much responsibility for the provision of proper dietaries. They would also need to coöperate with the voluntary hospitals and be able to provide good hospital accommodation for tonsils and adenoids. Health visitors, who had hitherto acted as relief officers, without proper liaison with the poor-law officers, would now be relieved of the undesirable duty of making inquiry into the financial circumstances of the people they visited. Such inquiry for assessing relief must now be done scientifically by one body, and one register must be kept for the purpose of all kinds of assistance.

Dr. **W. M. ASH** (M.O.H., Derbyshire) described a scheme for a complete maternity service within his county which had been already initiated. The scheme made use of existing institutions, and his survey had shown that there were hospitals in existence within five miles of every home. He proposed that, in lieu of building new institutions, additional bed accommodation for maternity cases should be provided at these existing hospitals. The staff of these hospitals would [illegible] midwives for intern and extern services and [illegible]taff of nurses, separate from the midwives, who [illegible]ld do district work. An ambulance would be provided at each hospital and the services described would be available by use of telephone and motors for domiciliary purposes within a radius of five miles. Home helps would also be sent out from the hospitals when needed, and sterilised outfits. Married midwives and home helps might live near the hospital and not necessarily in it. All antiquated poor-law buildings must be discarded and the new medical services made attractive. They must endeavour to secure the full *coöperation of all voluntary institutions* and bodies such as the Red Cross.

ABORTION.

Mr. **C. J. HAWORTH** (coroner for the West Riding) brought to the notice of the medical officers of health the increasing number of procured abortions, followed by illness if not death. Into one hospital in one year from a village with a population of 15,000 some 67 women were admitted suffering from incomplete abortions. None of these died, but, following inquests on some deaths in a neighbouring village, the epidemic of abortions in the first village ceased. It was significant that when there had been a conviction there was a lull of miscarriages in the district where the offence had been committed. Miscarriages in his opinion should be made notifiable. It was the clear duty of any medical practitioner when he was called in to a case of criminal abortion to report the matter to the proper authority.

SYPHILIS IN PREGNANT WOMEN.

Mr. **JOHN ADAMS**, F.R.C.S., described his experience at Thavies Inn V.D. centre. All the patients admitted are pregnant women affected with syphilis. Mr. Adams quoted from a paper by Sir F. W. Mott in 1912 and from the report of the Royal Commission on Venereal Disease, 1913, to illustrate the disastrous results of antenatal syphilis. The report stated that in the case of untreated syphilitic pregnancies, 50 per cent. of the fœtuses were stillborn, 75 per cent. of the living children died within the first year, mostly in the first week, and most of the remaining 25 per cent. died in early childhood. As a contrast Mr. Adams submitted a table showing the results obtained in all the cases of syphilis treated at Thavies Inn from September, 1917, to June, 1929:—

Cases treated.	Expected mortality of untreated cases*	Babies born alive. W.R.		Actual mortality.	Fœtuses born dead from syphilis.
		Pos.	Neg.		
267	178	86	159	1917–1919..4 1928..1 } 5	14

* See Royal Commission, V.D. Report, 1913.
W.R. = Wassermann reaction.

The treatment of the syphilitic mother and of the living child born to her should begin at the earliest possible moment. He often began the treatment of the child within half an hour after birth. If the treatment of syphilitic babies was begun at once and continued for a sufficiently long time they compared favourably with ordinary healthy children. (Mr. Adams showed photographs to illustrate the results obtained.) The procedure usually adopted to obtain blood from babies for the Wassermann test was difficult, dangerous, and often unjustifiable. (Mr. Adams described his method which was quite easy, and showed the special needle with an arrow-shaped point which he used.) Of the syphilitic cases admitted to Thavies Inn from 1917 to 1929, 1 in 12 had gonorrhœa in addition, but the gonococcus was found microscopically in less than 10 per cent. of the patients so suffering. Mr. Adams went on to describe the treatment adopted for gonorrhœa and for the prevention of ophthalmia in the baby. During ten years at his centre there had not been a single case of gonorrhœa ophthalmia. With our knowledge of this power of saving infant life, it was almost criminal that more was not done by the setting aside of institutional accommodation for these cases, and arranging for teaching to medical students and practitioners the special measures needed.

THE POPULAR LECTURE.

"Many Men, One Aim."

Prof. W. W. JAMESON said that with some justice we spoke of ourselves as pioneers in public health, but that, with our record of past achievements, we were inclined to be just a little complacent, and to give insufficient heed to the doings of other nations. By studying other peoples' methods we should be able either to improve our own, or to feel assured that we were working on the best lines possible. Dr. Jameson went on to give a most interesting account of the work of the public health services in Germany, in Poland, and in the U.S.A., and concluded with a quotation from a speech of Dr. Vincent, the president of the Rockefeller Foundation, describing an ideal internationalism that can hardly be bettered, in which "a generous national rivalry plays an even larger part without weakening true patriotic feeling. To contribute to a common world fund of knowledge, skill, and idealism becomes the ambition of each nation. Patriotism gains a nobler significance."

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE.

THE OPENING OF THE NEW BUILDING.

THE new building of the London School of Hygiene and Tropical Medicine was formally opened on Thursday, July 18th, by H.R.H. the Prince of Wales. The building was fully described in THE LANCET last week (July 20th, p. 149), with illustrations showing the important façades on Gower-street and Keppel-street, and the splendid library, and at the same time the origin of the school, the part played by British workers in its organisation, and the immense debt incurred to the Rockefeller Foundation were recorded.

The proceedings commenced with the reception of the Prince of Wales at the main, or Keppel-street entrance, by Lord Melchett, Chairman of the Board of Management, Sir Holburt Waring, Chairman of the Court of Governors, and Sir Gregory Foster, Vice-Chancellor of the University of London. The Director of the School, Dr. Andrew Balfour, was presented to his Royal Highness, as were the architects of the building, Mr. Morley Horder and Mr. Verner O. Rees, who offered the Prince of Wales the key of the building.

The Address of Welcome.

In the beautiful library a large and representative group of visitors were assembled to hear an address of welcome to the Prince, offered by Lord Melchett. The speaker pointed out that those responsible for the management of the School had embarked upon an enterprise made possible only by the benefaction of the trustees of the Rockefeller Foundation, which had realised that the claims of London as a centre for the teaching of hygiene and tropical medicine were unparalleled, and that assistance to provide the building of a central institute was therefore urgent. Lord Melchett reminded the audience that when three years ago the foundation-stone of the building in which they stood was laid by Mr. Neville Chamberlain, then Minister of Health, the American flag was flying side by side with the Union Jack above their heads, and the same was occurring to-day as a fitting reminder of their debt to American generosity. The absence from the ceremony of any representative of the Rockefeller Foundation was, he said, characteristic of the self-effacing policy of that establishment, while the Ambassador of the United States unfortunately had another engagement which could not be cancelled. Lord Melchett continued:—

"The gift of the Foundation followed immediately upon, even if it was not the direct consequence of, the recommendations of a committee which met in 1921 under the presidency of a distinguished relative of your Royal Highness, the Earl of Athlone. The committee found the arrangements for teaching for the Diploma of Public Health in London scattered and inadequate. The great post-graduate teaching centre which the Athlone Committee visualised as a necessity at once became possible by the fact that the trustees of the Rockefeller Foundation offered the munificent gift of $2,000,000 for carrying out the project which the Athlone Committee recommended. In this way it became possible that hygiene and public health should have a university institution of its own. And when further in the course of our deliberations the Seamen's Hospital Society expressed their willingness that the old School of Tropical Medicine should become merged in the institution, we felt indeed that these great twin subjects of hygiene and tropical medicine had at last their long-sought opportunity, and that a new epoch in the history of medicine and related sciences, and in hygiene, was about to be opened. Mr. Chamberlain at the foundation-stone laying, reminded us of the distinguished part which his father, Mr. Joseph Chamberlain, had played in founding, at the instance of Sir Patrick Manson, the School for the study of diseases of the tropics, and it is a pleasure again to recall this fact. We shall continue to be indebted to the Seamen's Hospital Society for clinical and pathological facilities for the study of these diseases, now that we have entered into our new home." The speaker went on to point out that to-day the presence at their gathering of Mr. Chamberlain, the ex-Minister, and Mr. A. Greenwood, the present Minister of Health, was evidence that the School which, in union with the University of London, would be partly maintained by Parliamentary grants, and be open to all nations, would be in a position where party politics played no share, a position that was necessary for the establishment of the laws of health. It was, he concluded, the future duty of the British public and British Government to see that the School was adequately maintained.

The Prince's Speech.

The Prince replied to the address of welcome by formally declaring the building open in the following words:—

"You have right to be proud of the magnificent building in which we are, and if the museums and theatre and laboratories make good the promise of this library, you are to be congratulated upon a building that will be a notable addition to the homes of learning in London. While the part played by America has been described to you, the duty lies on both the British Government and the British people to see that this School is worthily endowed and maintained. The building is a sign that post-graduate education in medicine is about to come into its own. The establishment and endowment of this centre of teaching in preventive medicine is a signal example of the bond between the two great English-speaking races of the world. The chairman has rightly said that there are no territorial frontiers in hygiene. The instruction in the class rooms and laboratories of this building will be conveyed by medical practitioners of every nationality to the far corners of the earth. This research will find its results wherever man lives and moves and has his being.

"Three periods in medical science are stamped definitely, each with its own characteristics. The first, from 1870 to 1900, was a period of sanitary reform. The next period was marked by growing concern for the protection of the individual, which had been the basis of recent legislation, as evidenced by maternity and child welfare, the treatment of tuberculosis and National Health Insurance. We stand now in the early days of an era of preventive medicine in which the progress made in sanitation and care of the individual will be developed, and fresh research will lead to the solution of problems not yet solved and to the prevention of much ill-health. The establishment of this school is of special importance to the British Empire, and it has undertaken great responsibilities. In my travels I have learned personally the appalling loss of life and effort due to tropical diseases, and I realised the great need for research in tropical medicine and hygiene. In the cause of hygiene generally the school will help and develop the growing work that has already been done. For these reasons I believe that the establishment of this school provides a great opportunity for this country and for the whole world.

"If its work is properly conceived and carried out, there should follow a special development and interest, and a quickening of the public conscience, which will lead to a steady decrease in preventible diseases, suffering and death. By its work in this connection the school will be judged."

The Addresses of Thanks.

A fanfare of trumpets sounded by the Coldstream Guards followed, when an address of thanks was presented by Sir Holburt Waring. Sir Holburt pointed out that throughout the erection of the building, and in every stage of its rise, the notion of a workshop had been kept clearly in view all the time. He said that the London School of Hygiene and Tropical Medicine was intended to be a centre of Imperial effort, and alluded to the pertinent fact that already the Court of Governors, as part of a policy of future development, had taken over from the Government of Southern Rhodesia the research station there. It would, he knew, be the policy of the School to establish a chain of such research stations throughout the Empire as adequate funds were forthcoming, and to send out expeditions from time to time to the tropics. As Chairman of the building committee he recalled that at the conception it had been decided that the first condition laid down for competing architects should be "Let there be Light," and in the employment of half a million sterling real concern he believed and hoped had been shown to make the expenditure wide and judicious. The Director of the School, the professors, and the departmental heads had throughout been consulted in the construction of their laboratories and workshops, and it had not been found necessary, thanks to the generous measure of the Rockefeller gift, to refuse a single request for any piece of essential equipment. He associated the Director, professors, and staff with the governors and the board of management in thanking His Royal Highness for the encouragement and inspiration of his presence.

Sir Gregory Foster, also, in thanking the Prince, said that the new School would rank as a part of the University of the metropolis—the University of the capital city of the Empire—and that its work would be organised, not for London, and not even for the Empire, but for the world. In alluding to the many great men who had been educated at the University of London, and who had gone forth to make the world a better and happier place, he said he would mention one name only, that of Lord Lister, who was a graduate of the University of London, and received his education in London. The Vice-Chancellor described in humorous terms the curiosity that had been aroused in the neighbourhood by the new building, the reason for whose existence the local public had not yet grasped, while he was certain that the new School would increase the tradition of magnificent service in the cause of humanity which the University of London possessed, by sending back students, who had arrived from all parts of the world to be taught, as missionaries of health.

His Royal Highness then visited the museum, the laboratories, and the lecture theatre, and before leaving the building met the workmen employed in its construction who were having their mid-day meal in a tent adjoining the premises. Here the health of the Royal visitor was drunk in beer with musical honours.

A large number of those who were invited to be present at the opening ceremony remained to luncheon as the guests of Lord Melchett, and afterwards, under the supervision of the Director, professors and members of the staff were shown around the building, and were present at cinematograph displays in the lecture theatre.

Reviews and Notices of Books.

ENZYME ACTIONS AND PROPERTIES.

By ERNST WALDSCHMIDT-LEITZ, Institut für Biochemie, Deutsche Technische Hochschule, Prag. Translated and extended by ROBERT P. WALTON, Department of Organic Chemistry, Columbia University. London: Chapman and Hall, Ltd. New York: John Wiley and Sons, Inc. 1929. Pp. 255. 20*s.*

THERE are many books upon enzymes. Some of them are almost entirely theoretical and physicochemical; others are laboratory handbooks giving methods for the preparation of active ferments from their natural sources; others are largely catalogues of facts. This volume falls into none of these classes, but sets out to describe enzymes and their actions from a definite point of view—that of the Willstätter school. Prof. E. Waldschmidt-Leitz has played a considerable part in the brilliant series of researches on enzymes carried out during the last ten years by Prof. Willstätter and his associates at Munich, and his book has the value to be found only in the work of one who has himself had practical experience of the problems involved. In order to appraise the book it is necessary to consider in what respects the work of Willstätter differs from that of his predecessors. In the first place, he has set out to place the preparation of enzymes on a quantitative basis, such as is customary in experiments in synthetic organic chemistry, for example, and he has considered in all cases the number of units of enzyme activity recovered after purification as well as the unit-weight of the enzyme preparation. This outlook led to a greatly increased efficiency in the various steps used in purification. Many of the methods employed by Willstätter are based on selective adsorption of the enzyme on to various substances such as alumina and kaolin, and subsequent removal (elution), usually by alteration of the reaction of the medium. Such processes are not new, but in the hands of Willstätter and his colleagues they have led to some remarkable results, such as the separation of enzymes from their closely associated contaminants, from activators, and from other enzymes. Willstätter considers that the enzymes are composed of a colloidal bearer and a specific, active group, which enables them to be bound to the substrate, and the composition of the active group at the same time conditions the colloidal nature of the entire complex. One of the most striking facts which have emerged from Willstätter's researches is that the properties of the enzyme are often profoundly modified by their intensive purification. Thus the conventional view regarding the higher protein fission products as the specific substrate of trypsin, which only hydrolyses these substances in the presence of the activator enterokinase, has received a rude blow from some recent work of this school. Trypsin prepared by adsorptive methods did not attack ordinary peptides when activated by enterokinase; on the other hand, certain basic proteins, such as the protamines and also the products of peptic digestion, are rapidly broken down even by the non-activated enzyme. In other respects the conventional views receive short shrift from Prof. Waldschmidt-Leitz. Most text-books, even quite modern ones, state unequivocally that the gastric proteolytic enzyme is secreted as an inactive zymogen known as pepsinogen or pro-pepsin, which is converted to the active form by the action of the hydrochloric acid in the stomach. This view is based on the observed effect of acid (which may more logically be regarded as a pH effect), and the varying stability to alkali of the active and inactive forms. This variation of stability may, however, be due to different amount of associated substances in the enzyme solutions under comparison. In any case the evidence in favour of a zymogen precursor is very small.

The critical outlook of this excellent book will be clear from these examples. Its contents are well arranged and are divided into a general section, dealing briefly with the history of the subject, with enzymes considered as colloids and as electrolytes, and with the kinetics of enzyme action. The other half of the book deals with the various enzymes individually. Their preparation and properties are well described, again from the Willstätter standpoint.

To those who wish to read in a connected form the conclusions reached by this important body of scientific workers, this work can be strongly recommended. We dissent from the view of the translator that, among others, students of medicine will find the volume of service. In our opinion it is essentially a volume for the research worker, since though its pages show how unwarranted is the dogmatism of the ordinary text-books where enzymes are concerned, much of the teaching would hardly be well received by examiners at the present time.

VIRUS DISEASES.

Les ultravirus et les formes filtrantes des microbes. By Dr. P. HAUDUROY, Préparateur à la Faculté de Médecine de Paris. Paris: Masson et Cie. 1929. Pp. 392. Fr. 40.

THIS monograph, which is the first on the virus diseases to reach us from France, starts badly, but improves as it goes on. The first part consists of a catalogue of the diseases and a summary of the known properties of the filterable viruses to which they are attributed. The information is neither happily selected nor critically presented. This part of the book, in fact, illustrates well the lack of system which has characterised the investigation of the agents of these diseases. The second portion is better compiled, and provides a comparative survey which is well worth reading. The author's views as here presented are on the whole orthodox. A serious defect is the absence of a bibliography. In the third portion of the book more rein is given to the imagination, and a very interesting thesis is developed. It is pointed out that many diseases of this type are definitely associated with certain micro-organisms which in our present stage of knowledge are not believed to be causal but commensual—in the French phrase they are "microbes de sortie." One would instance the almost specific salmonella in hog-cholera, *B. bronchisepticus* in distemper and, perhaps, Pfeiffer's bacillus in influenza. Hauduroy holds, as a corollary to his belief in the existence of filterable forms of the visible bacteria, with which the third part of this volume deals, that these are really the causal organisms of the diseases which are initiated by the filter-passing phase of the microbe's life-history. The belief in such phases for the larger bacteria has obtained little adherence in this country, since it is held that no very convincing evidence of their existence has been produced. However, so long as we remember that the foundations of the edifice erected by Dr. Hauduroy are inadequate for its superstructure, no harm can result from a cautious exploration of its features.

CONJUGAL LIFE.

Ideal Marriage. By TH. H. VAN DE VELDE, M.D. Translated by STELLA BROWNE. London: Heinemann (Medical Books) Limited. 1928. Pp. 325. 25s.

IN view of the increasing tendency to seek for an elucidation of neurotic disorder in terms of disharmony of the sexual life, a good book by a responsible medical authority, written for medical readers, upon the physical aspects of marriage, should satisfy a need. Dr. Van de Velde has for some years been in charge of the Gynæcological Clinic at Haarlem, and this book has been written as a result of the experience gained in the days of his professional activity. This is the first of a trilogy of books and purports to deal with the sexual basis of married life. The second book of the trilogy will be called "The Prevention of Conjugal Aversion," and the third, "Fertility and Sterility in Marriage." "This first volume," it is stated in a preface, "deals with the physiology of conjugal life, because knowledge is the indispensable basis, both theoretical and practical, for success in marriage"; and its chief value rests in the frank and open way in which it discusses the conduct of marital relations.

It falls short of the ideal book for medical men in this, that whereas its sale is restricted to the medical profession in this country, it was not originally written, in German, for the medical profession alone. This is acknowledged in the preface, wherein it is stated that the book "attempts to help such married couples as have not recourse to doctors, without their intermediary advice." Actually this book has enjoyed a very considerable sale in Germany, where it could at one time be bought on most bookstalls. The result of this circumstance is that it contains some elementary anatomical descriptions that are likely to prove somewhat wearisome to the medical reader. Another drawback is that the style is pitched on a plane of ideality which is somewhat exalted for purely medical purposes. Thus, into the text are intercalated what the author, or the translator, has called three "Intermezzos of Aphorisms." These vary considerably in quality. They range from observations as excellent as "A husband's interest and honour alike enjoin that he should never permit himself a sexual gratification which he has not made his wife's desire as well," to other less edifying pronouncements.

In spite of these not very important defects, however, this book is to be recommended to those medical men who feel that disharmony in marriage is a source of mental stress or disorder to their patients, and who wish to equip themselves to give appropriate advice to remedy this disharmony, without having to read the ponderous volumes that are devoted to the study of sexology.

The Hygiene of Marriage. Second edition. By ISABEL EMSLIE HUTTON, M.D. Same publishers. 1929. Pp. 125. 5s.

THE first edition of this book was published in 1923, and an edition was also published in Dutch in 1925. To the practitioner who is asked by his patients for a work by a responsible author setting forth the facts of sexual physiology and psychology, this book is to be recommended. The anatomy and the physiology of the reproductive organs are explained in as much detail as is necessary, and the literary style is both simple and free from criticism. Despite its title, the book deals with the reproductive functions of woman as a whole. There are useful chapters on the onset of menstruation and the menopause which only very indirectly touch upon the question of marriage. Perhaps the most valuable feature of Dr. Hutton's book is that she makes the fullest allowance for the wide variations in sexual needs that occur in different people. Her method is to set forth the problem, and to leave the solution for the couple to reach in accordance with their personal characteristics. There are no generalisations made from religions or sociological preconceptions.

The book could offend no one seriously desiring knowledge and, suitably recommended, is capable of giving valuable help.

THE RHYTHMS OF LIFE.

By D. F. FRASER-HARRIS, M.D., D.Sc. London: George Routledge and Sons, Ltd. 1929. Pp. 185. 5s.

CERTAIN of these essays may have already met the eye of the reader, for they have appeared in well-known magazines and newspapers. They deal, in simple language, with such subjects—to select certain for example—as the eye as a camera, the comparative sensitiveness of the sexes, the analysis of tastes—i.e., of the true gustations, our debt to the microscope, and the cause of colour, the other themes being similarly large in their relation to life, and similarly likely to escape exact comprehension until attention is directed to their problems—scientific or social. The volume makes excellent reading, for in sound but colloquial manner it deals with fundamental questions arising out of physiology, chemistry, and physics. Dogmatism is necessary in order to deliver the messages with appropriate brevity, but on the whole the teaching that the author lays down would find scientific support, although there are places where modern developments of particular branches of science have somewhat altered our views. Such essays as that on the cause of colour and that on the analysis of tastes, as well as the opening chapter which gives a name to the book, have real educative value, supplying information where the imperfectly equipped are perpetually puzzled.

HANDBOOK OF ANÆSTHETICS.

Third edition. By J. STUART ROSS and H. P. FAIRLIE. Edinburgh: E. and S. Livingstone. 1929. With 60 illustrations. Pp. 339. 8*s*. 6*d*.

THIS excellent little book has grown somewhat since its last edition and has now the advantage of Dr. H. P. Fairlie's coöperation. He has added a chapter on ethylene and oxygen and has brought other matters in the book up to date. The character of this work, which stamped it from the first as a really valuable handbook, has not changed. It is distinguished by an enlightened insistence on a proper knowledge of the physiological changes involved as the true basis of competent anæsthetic work, rather than a mere familiarity with a collection of apparatus. At the same time the essentially practical nature of the anæsthetist's activities are not forgotten. There is no small book better calculated to guide an administrator on safe lines.

THE GROWTH OF REASON.

By FRANK LORIMER. London: Kegan Paul, Trench, Trübner and Co., Ltd. 1929. Pp. 213. 10*s*. 6*d*.

THIS is the study of the rôle of verbal activity in the growth of the structure of the human mind, and is the most recent volume in the International Library of Psychology, Philosophy and Scientific Method; it might well be read in connexion with an introduction to child psychology, contributed under the title of the Growth of the Mind, by Prof. Koffka to the same series. Mr. Lorimer, who is lecturer on "social theory" at Wellesley Psychological College, Mass., U.S.A., approaches the problem of the relation of thought and language through a study of verbal activity in children, acknowledging the inspiration derived from Prof. Dewey of Columbia University, while other authorities, whom he mentions by name, he credits with his ability to elucidate various technical and psychological difficulties with accuracy.

After sketching the evolution of thought prior to the employment of active language, the author traces the growth of verbal activity in the life of the child. Vocal activity we know to be a conspicuous feature of the infant's career, but here we have voice under its physiological description of a form of modified breathing acting conspicuously—and nothing more. Sounds can only become words by virtue of a social process, and a valuable section of the book illustrates this process and leads up to the three following sections showing that verbal processes, spoken or silent, supply the dominant system of human intellectual life. This conclusion, says the author, involves three things: (1) The establishment of fixed "symbolic relations" between unitary phonetic patterns and patterns of situation and behaviour (which are lacking in the fluctual relations of the "first words"), so that words may function as *foci* or *substitutes* for organic patterns in the processes of intellectual experimentation; (2) the development of fixed *relations of order* and sequence in the verbal processes themselves (systems of reference and inference in systematic thinking); and (3) the capacity for more and more intricate *correlation* of intellectual processes, including explicit symbolic systems." Mr. Lorimer's expositions are easy to follow, although his plan of work is not, and we have here a valuable book in which the relation of social to organic factors in thought development is traced, the argument being furnished for the general thesis that while animals may live well by instinct, and primitive communities by culture patterns, civilisation can live well only by symbols and logic.

ANTHROPOLOGY AND MODERN LIFE.

By F. BOAS. London: George Allen and Unwin. 1929. Pp. 246. 10*s*.

ANTHROPOLOGY studies groups of human beings in relation to their social setting. Prof. Boas has had a long and distinguished career as an anthropologist and in this book he summarises his views of the relation of his science to our life to-day. He deals with race, nationalism, eugenics, criminology, education, culture, and related topics throughout in an interesting way. As befits the real student, the author is evidently more impressed with the problems which remain to be solved than with what we have found out already, and the reader will be struck with the absence of dogmatism and the open-mindedness of the discussions. He has no quack remedies for our social evils and deficiencies; all we can do, he says, is to watch what we do in the light of what we have learned and shape our steps accordingly.

DISORDERS OF CHILDREN IN INDIA.

Birch's Management and Medical Treatment of Children in India. Seventh edition. By V. B. GREEN-ARMYTAGE, M.D., F.R.C.P., and E. H. VERE HODGE, M.D., M.R.C.P. Calcutta and Simla: Thacker, Spink and Co. 1929. Pp. 482. Rs.10.

THE publication of this edition perpetuates a work, the continuity of which has been maintained for 75 years. Originally written by H. H. Goodeve in 1844, it was remodelled by Brigade-Surgeon Birch about fifty years ago, since when it has been revised from time to time. The present authors have introduced much new material, and have brought the book thoroughly up to date.

The practicability of bringing up European children in India is the first question likely to be considered by those who have to decide whether to spend their married life in that country, and they are likely to seek advice first from their family doctor. It is thus not only medical men practising in India who may want to consult this work, the authors of which give clear information on the possibilities and limitations of family life in India. During the first year of life the child does not suffer injury; even up to the age of 5 or 6 the child's health may be perfectly satisfactory if special precautions are observed; but after this age the climate of the plains conduces to physical and moral degeneration. Children brought up entirely in the hills are in no way inferior to those brought up at home. The book contains short accounts of the disorders of childhood, and is not limited to purely tropical diseases. The chapter on rickets suggests that this disease is not as rare among any section of the Indian community as has sometimes been alleged. Infective bowel complaints are dealt with in some detail, and emphasis is laid on the extreme rarity of amœbic dysentery in children as compared with bacillary infections. The chapter on malaria is a particularly valuable one, the practical details of the treatment and its numerous difficulties being fully discussed. The authors disapprove of the routine use of quinine as a prophylactic.

This is a work for which there is likely to be a large demand, not only among practitioners but among educated Europeans who are faced with the problem of rearing children in India.

THE LANCET.

LONDON: SATURDAY, JULY 27, 1929.

AFRICA AND SCIENCE.

THE ninety-ninth meeting of the British Association for the Advancement of Science began in Cape Town on Monday; the concluding assembly will be held in Johannesburg on August 3rd, after which the members and visitors will disperse to visit some of the wonders of the continent. The whole affair will no doubt be a great success, and we can envy those who have been lucky enough to get there. While we wait their traveller's tales, we can get some idea of the atmosphere in which they are from the prints of the various addresses which are available. Nothing, perhaps, in these is more remarkable than the expression of the feeling that, just as facilities of travel have made a meeting in South Africa an easy possibility, so it has become the proper business of natural science to concern itself directly with humanity and its welfare; politics in the widest sense is now one of its disciplines. In his presidential address on the International Relationship of Minerals, Sir Thomas Holland, as might be expected from so practical a man, goes straight to the point, and shows how the control of mineral products means the control of war and peace as well as industry; it is a new departure to find the President's discourse leading to the conclusion that "the only two nations that can fight for long on their own natural resources are the British Empire and the United States; if they agree in refusing to export mineral products to those countries that infringe the Kellogg Pact, no war can last very long."

Africa is full of the varied problems raised by the intimate contact of advanced and backward peoples—by man's passion for interfering with the order of nature—and it is natural that the Association should pay a good deal of attention to these questions in the sections of anthropology, economics, and elsewhere. Philologists, economists, and cellular cytologists are all involved, and if their combined efforts can do something towards a happy issue, the advantages of such organisations as the British Association, which bring together workers and thinkers of so many different complexions, will be admirably illustrated. To consolidate the humanities of Africa into a coherent and harmonious civilisation will realise in the best way the doctrine of holism set out by General J. C. SMUTS—South African, botanist, philosopher, and statesman. The address of Vice-Chancellor J. H. HOFMEYR, with which the proceedings actually commenced, is perhaps of more local interest. He points out the opportunities which are available in Africa for opening up our knowledge of every branch of human interest. The apparatus and equipment—human and material—for the pursuit of natural knowledge, have been enormously increased since the last visit of the Association in 1905, and curiosity has grown with the chances of satisfying it; from the more narrowly economic as well as the wider scientific points of view, Africa is now at least as useful as any other part of the world. In our own extensive field, our readers will hardly need to be reminded on the one hand of the magnificent institutes for veterinary and medical research and on the other of the contributions which the study of trypanosomiasis, sleeping sickness and other diseases have made to our general knowledge of infections. South Africa is now being Africanised, it is acquiring a culture and outlook of its own, and in many ways it can and will help the rest of the world. Of the more immediately biological addresses, we give an epitome of Prof. W. E. DIXON'S discourse on Physiology the Basis of Treatment on another page; Prof. A. C. SEWARD deals with fossil botany and the correlation of African with more northern strata; in Zoology, Prof. D. M. S. WATSON points out that while the fact of evolution is now believed in more firmly than ever, the mechanism of it seems more and more obscure, and he suggests that it is time to get nearer the basis of adaptation by a more intensive study of comparative physiology. Dr. J. S. HALDANE, General SMUTS, Prof. D'ARCY THOMPSON and others will discuss the Nature of Life, and may or may not succeed in getting nearer to finding out what it is.

GLYCOGEN, INSULIN, AND EPINEPHRINE.

GREAT as is the therapeutic and scientific value of the discovery of insulin it has not as yet simplified the physiology or pathology of diabetes. The cause of metabolic failure in diabetes is still to seek and there are many other problems which have resisted solution in spite of the new knowledge. Insulin has not proved to be a master key, but it has opened many doors and it has closed others by showing how slender is the evidence upon which certain orthodox ideas about carbohydrate metabolism are based.

In the lectures recently delivered by Prof. J. J. R. MACLEOD at the London Hospital, and published in our columns,[1] the results of recent work are set out in some detail. The fate of ingested soluble carbohydrates is of particular interest and some remarkable differences have recently been observed in the rate of absorption of different sugars. When these are given by the mouth absorption occurs very rapidly from the upper level of the small intestine, and according to C. F. and G. T. CORI the amount absorbed per hour per 100 g. of body-weight has a definite value for each sugar. Peritoneal absorption, on the other hand, appears to depend merely on the concentration of the sugar solution. The effect of ingested carbohydrate on the blood-sugar is well known clinically from the use of the glucose tolerance test, and the ingestion of lævulose and galactose has been studied in tests of liver efficiency. The fact that the consumption of these substances has such a slight effect on the sugar content of the blood, if the liver is working efficiently, is assumed to be due to the rapid polymerisation of these sugars to form glycogen by the action of the normal liver. But even the explanation of the presence of glycogen in the liver is still unknown; is it a simple storage of carbohydrate or is it, as CLAUDE BERNARD thought, a type of internal secretion, by which the glycogen is produced in the liver cells from non-carbohydrate sources? It is well known that new formation of glycogen, from protein or fat, or both, occurs in the liver during starvation, but it has generally been thought that the liver glycogen disappears when the fasting animal is made to do muscular work. This result has not been confirmed by some recent work discussed by Prof. MACLEOD. It is also questionable whether in pathological conditions glycogen ever disappears completely. The storage hypothesis does not explain the action of epinephrine and insulin on the liver glycogen. Epinephrine causes deposition of glycogen in the fasting animal and the breakdown of glycogen in the liver rich in this substance. The mechanism by which insulin acts is not yet clear, though it is now seven years since its remarkable property of lowering blood-sugar was first used therapeutically with miraculous success. Diabetes has often been attributed to a failure of the organism to oxidise carbohydrate. This is supposed to be shown by the low respiratory quotient, lack of ability to store glycogen in the liver, and excessive new formation of glycogen from non-carbohydrate sources. This view, based mainly on determinations of the dextrose-nitrogen ratio, has not in all respects been confirmed by recent work, and there are objections to some of the arguments brought forward in its favour. There is, moreover, some evidence that the diabetic animal is able to utilise the blood-sugar at approximately the same rate as the normal animal, though perhaps not to oxidise it at the same rate. It is possible that much evidence based on measurement of the respiratory quotient is unsound in view of the over-ventilation of the blood in the lungs in the eviscerated preparations used. I. L. CHAIKOFF and MACLEOD have found that the respiratory quotient following increased muscular activity is the same in normal as in diabetic animals. The total evidence available does not support the view that insulin merely acts by direct stimulation of the oxidation of carbohydrate. Nor is it possible as yet to say what is the fundamental cause of the metabolic failure. One theory is that only the glucose produced in the liver is excreted in diabetes, and that the diabetic muscle is unable to oxidise this glucose, although it can use it for glycogen formation. This is, of course, contrary to the usual view that the diabetic animal derives its energy from the combustion of fat and protein. At present all that is definitely known is that insulin given to diabetics causes glycogen to appear in the liver, whether or not carbohydrate is given to the animal.

---

[1] THE LANCET, July 6th, 13th, and 20th.

In normal persons the muscle glycogen seems to be dependent in some way on the liver, while C. H. BEST, J. P. HOET, and H. P. MARKS have shown that glycogen formation following the addition of glucose to the blood can occur in muscle in the presence of insulin. Insulin is not, however, essential to the process, since glycogen is formed in the muscles of depancreatised animals. Experimental evidence suggests that either glycogen formation in the liver or increased production of insulin from the pancreas may be an essential preliminary to the formation of glycogen in the muscles of normal warm-blooded animals. The breakdown of glycogen in muscle has long been associated with muscular exercise; in a spinal animal the glycogen content falls when the muscle is stimulated. MACLEOD and FRASER, however, have recently shown that in rats working steadily the oxygen requirements of the muscle are adequately met and the glycogen need is sufficiently provided for. Only when the activity is so great that the oxidation of carbohydrate is defective does the glycogen content become appreciably lowered. These are only a few of the problems raised by the conflicting results of experiments devised to test theories of carbohydrate metabolism and to explain or confirm clinical findings. Luckily the impetus given to this study by Prof. MACLEOD, to whom the original researches of BANTING and BEST owe their initiation, shows no sign of slackening and it is unlikely that its force will be spent until the pathology of diabetes is cleared up, even if the exact biochemical changes involved cannot be repeated in the laboratory.

◆

DROUGHT IN THE THAMES VALLEY.

THE effects of a dry summer following a dry winter are beginning to make themselves felt in the Thames Valley, although not to the same extent as in some other parts of England. With the recent memory of floods in the mid-reaches of the Thames it is difficult to visualise the fact that the rainfall of the past few months has been abnormally low, lower in fact than in any year since 1921, when the drought lasted until the end of August, to be succeeded by a gush of water which might have imperilled the public health, although it did not. Very little water is passing over Teddington weir, and the pool below consists practically of the same water which oscillates to and fro with the tide; the whole watershed of the Upper Thames is draining directly into the reservoirs which supply London with water; but even the immense new Littleton basin is not inexhaustible. We are assured that the Metropolitan area is not threatened with any immediate deficiency in supply, and although the Trafalgar Square fountains have stopped playing, as an object-lesson (they do not really use up water), local authorities have hesitated to issue appeals for economy because they feared to create an atmosphere of panic. We have not, in fact, arrived at the time when families must reduce their personal ablutions to a minimum, and use slop water for watering plants and garden, but the time has arrived when every patriotic householder will adopt altruistic principles in relation to public water-supplies, and avoid any unnecessary or luxurious use of tap water. To the majority of Londoners water only becomes attractive at the height of a heat-wave, and the consumption per head went up last week at least 25 per cent. over the average. Some time we must try to reach a tangible conclusion as to what is a reasonable rate of consumption per head of population in summer and winter, for the increased storage could no doubt be provided at a price, although the price might be so colossal that some adjustment of the personal water quota would be the thing to aim at. The way in which water was economised in the summer of 1921 was little short of amazing, and there was no evidence that the health of the community suffered in any way as a result of the drought, though their convenience and sense of well-being may well have been adversely affected by change of habits. Probably the restriction could have been carried much further than it was without serious harm. The violent outpourings of the last week-end should also remind the community of the risks of pollution when the dry period comes to an end, and the surface gathering grounds are subjected to sudden heavy rainfall. The value of chlorination under such circumstances has now been proved up to the hilt; it is far more effective than any possible injunction to the public to boil water when there

---

[1] Metropolitan Water Board. Twenty-third Annual Report on the Results of the Chemical and Bacteriological Examination of the London Waters for the twelve months ended 31st Dec., 1928. By Sir Alexander Houston, Director of Water Examination. London: P. S. King and Son. 21s.

should be a doubt about its purity, an injunction which is sure to be unobserved just where the necessity is greatest.

Compared with many rivers of the Continent of Europe, *to say nothing of such streams as the Nile or* the Amazon, the Thames may be an inconsiderable stream, but Sir Alexander Houston[1] tells us that in its course from Staines to Hampton the Metropolitan Water Board abstracts 152 million gallons of water a day, or, to put it in pictorial form, more than enough water to supply at 85 gallons per head daily the needs of Bradford, Birmingham, Glasgow, Liverpool, Manchester, and Sheffield. River water, unfortunately, has to be filtered and disinfected, but it is gratifying to know that the two million people who have been supplied with chlorinated Thames water since May, 1916, have not complained about the taste of it. Treatment with liquid chlorine of the water on its way from the Staines reservoirs to Sunbury, instead of the old plan of adding bleaching powder at Staines itself, has not only been effective in eliminating the colon bacillus, but has been economical in practice, since it increases the volume of water which can be passed through a filter before it has to be cleaned out. It may be remarked in passing that it costs £40 to clean an acre of filter-bed. But although chlorine has thus come to be accepted by the London water drinker, there have been flavours and colours in the water which have troubled the Water Board. Several years ago the water from the Barnes works acquired a taste euphoniously described in the laboratories as "geranium-like," but more pointedly by the consumers as resembling rotten fish or castor oil. This taste was completely removed by the addition of 2½ to 5 pounds of potassium permanganate to every million gallons of water, the faintly pink tinge of the water soon disappearing, leaving behind only a slight brownish discoloration. The malefactor in this case was the troublesome but harmless tabellaria. A few years previously another harmless growth, oscillaria, developed to such an extent in the filter-beds that they looked as though they had been fouled with green paint; in this case a small dose of copper sulphate proved sufficient to eliminate the mischief.

Chlorination has not, it appears, been such a success in the other sources of London water. In the New River the colon bacillus, after its apparent removal at Crouch End, has reappeared by the time the water leaves the Stoke Newington reservoir and the cause of its reappearance is not yet clear. Of bacterial contamination the presence or absence of the typhoid bacillus is of the first importance, and it is reassuring to find from a long series of experiments with the glucose-bismuth-sulphite-iron medium described by Wilson and Blair, and later by Prof. Wilson at the Public Health Congress in 1928, that Sir Alexander Houston is convinced not only of the value of the medium, but of the practical absence of this organism in 100 c.cm. of raw river water, and by inference in one thousand times that amount of purified water.

THE KING.

It is satisfactory to learn that during the week following his operation on July 15th the King has made steady progress. The fact that purulent discharge from the abscess has already ceased shows that the measures taken to promote drainage were fully justified and have achieved speedy success. The inconvenience and discomfort of the first few days following any operation are not negligible, but the fact that the King was allowed to sit up for a short period as early as last Monday, and for some hours on Tuesday, shows how little his general health has been disturbed. We are entitled to hope that his complete recovery is now only a matter of time, and that no further interference will be required.

Annotations.

"Ne quid nimis."

THE ROCKEFELLER FOUNDATION: A NEW CHAPTER.

In 1909 the Rockefeller Sanitary Commission was established for the control of hookworm disease in the United States, and in 1913 the Rockefeller Foundation came into existence, taking over the Sanitary Commission. After 16 years of intense activity entailing the total expenditure of over 144 million dollars the Foundation has opened a new chapter by certain steps of extension and reorganisation.

These changes are recorded in a review for 1928 by the President of the Foundation, George E. Vincent. He describes how during 1928 a conference committee of four Rockefeller boards—the General Education Board, the Rockefeller Foundation, the Laura Spelman Rockefeller Memorial, and the International Education Board—sought ways of bringing the work of these organisations into close and more definitely coöperative relations. In the autumn the committee made a report embodying recommendations which were approved by all the groups, with the understanding that the new *régime* would take effect at the beginning of 1929. Among the essential features of the reorganisation is the merging of the Laura Spelman Rockefeller Memorial into the Rockefeller Foundation, which will begin as a new corporation. This new Foundation will extend its activities to include not only public health, but the advancement of knowledge in the medical sciences, in the natural sciences (taking over the foreign programme of the International Education Board), in the social sciences (previously administered by the Memorial), and in the humanities. The public health activities will be administered in future through an International Health Division with a group of seven scientific directors and a China Medical Board is to be incorporated, with independent trustees, to which the lands and buildings in Pekin, together with endowment funds and annual appropriations, will be given. The details of this vast amalgamation and reorganisation of resources appear to be fully worked out, and if it is possible to imagine a further extension of the activities of the Rockefeller Foundation such an extension should now take place. To anyone unacquainted with the work done by the Foundation under the glorious motto of "The well-being of mankind throughout the world" a study of the review for 1928 will be illuminating. In one almost breathless sentence in which a full-stop does not occur for nearly two pages, it is announced quite bluntly that the Foundation in 1928 expended over 21 million dollars on some 20 different forms of activity. Each of the 20 headings covers large areas of country and large pieces of work.

A sample of the methods and policy adopted is given in a description of the Lyon Medical Centre. At Lyon the municipal authorities have under construction a large new hospital; the Foundation was asked to coöperate in providing an adequate medical centre for education and research. The first step was to invite the dean with two of his staff and the university architect to visit medical centres in various countries as guests of the Foundation. The commission returned to Lyon, worked out a plan, and as a result of this a medical school building is being erected immediately across the street from the new hospital, while the project also includes an increase in the annual budget to improve teaching facilities and the provision in the hospital of laboratories for the clinical subjects. Towards the cost of this project, to which the Government, the municipality, the university, and private citizens contribute, the Rockefeller Foundation has appropriated or pledged 43 million francs.

HEALTH INSURANCE IN THE IRISH FREE STATE.

THE text of the National Health Insurance Bill recently introduced to the Dail was published last week. The only proposal of any importance in the Bill, writes our Dublin correspondent, is that to abolish county insurance committees and to transfer their functions to the county councils, which will be provided with funds to enable them to perform their increased duties. Certain other proposals tend to simplify the working of the Insurance Acts and to lessen the expense of their administration. The deposit contributors' fund is to be abolished, and members of this fund are to join approved societies within a specified period. The difficulties which have hitherto existed regarding insurable married women are surmounted by giving an insured female a marriage benefit, and providing that if she desires to work after marriage she will be treated as if she had never been insured. The Bill appears to be based on the recommendations of the Committee of Inquiry on National Health Insurance and the Medical Services, but it only touches on a few of the less important of the reforms suggested by that Committee.

AURAL DISEASE AND BATHING.

THE holiday season, which has now arrived, will doubtless be accompanied as usual by trouble—some minor and some serious, in the ears of bathers. Mammals such as the seal, which have reverted to an aquatic life, have a mechanism for closing the auditory meatus, and in some cases the nostrils also, when submerged; but man is not an aquatic animal and does not possess this form of protection. Water can reach the ear and cause damage to it either by way of the external auditory meatus or through the Eustachian tube. When water gets into the external ear it produces a disagreeable sensation, as every swimmer knows, but it runs out again quickly and does no harm in a healthy meatus. If, however, the ear contains much cerumen this imbibes the water, swells up, and blocks the canal. The sensation of "water in the ear," persisting long enough for advice to be sought, is nearly always due to wax, and can be cured by its removal. People with a tendency to excessive secretion of cerumen should have it removed before going to the seaside. This retention of moisture from the presence of wax readily sets up a dermatitis, and is the usual cause of external otitis in bathers, but apart from this people with a tendency to eczema of the meatus are apt to suffer an exacerbation of their trouble from bathing. Unskilful diving may rupture the drum by compression of the air in the canal, but in general the occasional entry of water into the meatus is harmless, as is evident from the comparative rarity of trouble among innumerable bathers. The most important cause of serious ear disease resulting from bathing is the entrance of water into an old, often quiescent, perforation of the drum; this event is liable to cause a very severe suppurative otitis with all its attendant complications. Patients with a perforated drum should never bathe without a really efficient means of preventing the entry of water into the ear. Ordinary cotton-wool is useless for the purpose, and, by giving a false sense of security, becomes a danger; to occlude the meatus a cast of the patient's concha specially made for each case can be obtained from instrument makers, but a plugging material made of a mixture of wool-fibre and plasticine or wax is very satisfactory and is sold by various chemists; a rubber bathing cap to cover the ears should be worn over any plug. Patients with a tendency to aural eczema may with advantage put in at night a few drops of mercuric nitrate ointment, 1 drm. to 1 oz. of equal parts of olive oil and liquid paraffin.

Nevertheless, people wit [illegible] ears may develop acute otitis me [illegible] s is caused by the entrance of [illegible] through the Eustachian [illegible] s favoured by swallowing while under water and, especially, by violent blowing of the nose, while the passages are full of water. It is when virulent micro-organisms are carried into the tympanum with the water that otitis ensues; these organisms may be present in the water, and it is obvious that the water of swimming pools and public baths is more likely to be heavily infected than that of rivers and the open sea. Much care has been devoted to the purification of the water of bathing places, but more attention has been paid, as evidence of contamination, to the intestinal flora of the *Bacillus coli* group, than to the pyogenic organisms which more frequently attack the ears; but it is probable that the swimming bath may play an important part in the spread of streptococcal infections when, for instance in a school, such diseases as tonsillitis or rhinitis are prevalent. Groups of cases, or small epidemics, of infection of the nasal sinuses have occurred under similar circumstances, and probably from the same causation. But micro-organisms can be carried with the water into the ear even when the water of the bathing place is perfectly clean; this occurs when the organisms are already present in the patient's own nose or throat, and is liable to result from bathing during an attack of sore-throat or coryza.

To sum up: Harmful results from bathing are very rare in proportion to the number of bathers; it is necessary to plug the ears only when there is an open perforation of the drum or when the canal is readily irritated by the water; ear complications are unlikely to occur from infection through the Eustachian tube if the bather refrains from swallowing while in the water and particularly from blowing the nose on emerging, and does not bathe at all while suffering from an active cold or sore-throat.

THE PROGRESS OF INDUSTRIAL PHARMACY.

IT would be hard to exaggerate the debt which modern medicine owes to the firms who manufacture the drugs and other preparations nowadays necessary for its practice. A century ago most clinicians and experimenters had to mix their own medicines and solutions; nowadays they can draw upon an arsenal of products compounded with the utmost care and standardised with extreme accuracy. If the activities of manufacturing pharmacists could be taken as a measure of the advance of medical science in modern times, that advance can hardly have been surpassed by any other branch of human activity. The annual special issue of the *Chemist and Druggist*[1] aims at providing a survey of the industry from all its aspects year by year, and should not be missed by anyone with a sense of the importance of this great auxiliary. Great pains have been taken with the reproduction of the many unique photographs. The chief articles in the industry of to-day deal with the manufacture of cotton-wool and lint at the mills of Messrs. Vernon and Co.; solid spirituous preparations, and the cultivation and preparation of the soya bean, a seed of ever-increasing value as a source of vegetable oil, and as a foodstuff. The issue also contains three first-class historical essays. Dr. Charles Singer contributes the second part of his "Sketches in the History of English Medicine," in which he describes the Anglo-Norman Period, and the advent of the learning of Salerno and the Arabs. This is illustrated with a large number of excellent contemporary pictures, including two splendid coloured plates. He gives an interesting quotation from the Prologue to Chaucer's Canterbury Tales; one which perhaps marks the first mention in English of the manufacturing pharmacist: "Full ready had he his apothecaries to send him drugs and his electuaries." Another article describes the pharmacological history of Dublin, where this year's British Pharmaceutical Conference was held, and the history of druggists' weights and measures through the ages is set out in an encyclopædic contribution illustrated with 84 photographs. Dr. Giovanni Carbonelli, of the National Medico-Pharmacological Institute in Rome, describes and illustrates the private pharmacy of Pope Alexander VII. The Editors are to be congratulated on an admirable production.

AN INDEX OF RENAL EFFICIENCY.

It has long been recognised that in certain types of advanced renal disease the ability of the kidney to excrete inorganic phosphates is impaired. In such cases the fall in phosphate excretion is accompanied by a corresponding increase in the concentration of phosphate in the blood and more than one attempt has been made to devise a criterion of renal efficiency based on the rate of elimination of injected phosphates. Working with dogs, Bolliger[1] has given intravenous injections of sodium phosphate solutions, of varying pH, and has found that the normal animal is able to excrete from 80 to 100 per cent. of the amount injected within two hours. After destruction of the major portion of the renal tissue, by exposing one kidney to X rays and ligaturing the opposite ureter, the excretion falls as low as 21 per cent. These results with dogs support the conclusions of R. T. Brain and H. D. Kay,[2] who have used intravenous injections of sodium glycerophosphate as an index of renal efficiency in human nephritis and claim that this test gives more valuable information than either the urea concentration or the phenol sulphonphthalein methods. Sodium glycerophosphate has the advantage over sodium phosphate of greater solubility and does not require adjustment of the pH. Since the acidosis which so often accompanies uræmia has been ascribed to the retention of acid phosphate, the wisdom of injecting phosphate solutions in nephritis may be called into question. Brain and Kay, however, find no ill-effects from glycerophosphate, while Bolliger finds that repeated injections of inorganic phosphate actually have a consistently beneficial effect in "nephritic" dogs, and suggests that similar injections may be of value in human nephritis. An adequate explanation of this anomaly is at present lacking, but Haldane, Wigglesworth and Woodrow have shown that large quantities of phosphate buffers help the kidney to excrete acids. It seems that the prevalent view, that phosphate injections are harmful in nephritis, must be revised and, if clinical trial bears out Bolliger's experimental results, we may find a new therapeutic weapon to delay the progress of nephritis.

THE LEPROUS REACTION.

The acute phase of leprosy has been the particular study of Dr. Richard Green, who has been in charge of the inmates of the Federal Leper Settlement at Kuala Lumpur, in the Federated Malay States, during the last three years. In a paper communicated to the Royal Society of Tropical Medicine and Hygiene, and published in their transactions (1929, xxii., 307), he notes his conclusions. He finds that the leprous reaction, especially in the so-called second stage of Muir, leads to rapid progress of the disease; rarely, the reaction may be of such severity as to lead to death. This acute phase of the disease may recur from time to time in both treated and untreated cases; it appears, however, to be more frequent in patients undergoing treatment with the oils of hydnocarpus and their derivatives. During the past three years about 20 per cent. of the patients undergoing treatment in Kuala Lumpur have had one or more reactions. The Kuala Lumpur Chinese leper patients appear to know and to fear the occurrence of the reaction. Their recognition of the phase is suggested by their native term for it, which means "the rising up of leprosy." Dr. Green has initiated experiments with intradermal tests, using *B. lepræ* obtained from freshly ground nodules under aseptic conditions, which appear to indicate the presence of specific sensitiveness of the tissues towards *B. lepræ* in cases suffering from leprous lesions, with an absence of this phenomenon in quiescent cases. The evidence collected in the course of his investigations seems to show that the leprous reaction may have its origin as an acquired condition of allergy towards *B. lepræ* in the tissues. This supposition appears to be strengthened by observations on the action of adrenalin, on the analogy of desensitisation in serum sickness and other allergic conditions. The continued administration of ephedrine seems to have little effect on newly formed skin lesions, though a number of patients complaining of nerve pains were given single doses of ephedrine hydrochloride gr. 1, with relief lasting twenty-four hours or more. In the absence of a specific for leprosy, any drug securing relief of pain, even for a short spell, is welcome, but continuous search is being made for one which will give a more prolonged spell of amnesia.

IN DEFENCE OF THE R.M.O.

The lively attack upon the habits, manners, and accomplishments of the resident medical officer, markedly in the special and medium-sized general hospitals, which appears over the signature of "Juno" in the current issue of the *Hospital Gazette* would be more wounding if it was plausibly true to life, while the suggestion that the average house surgeon is discourteous and inconsiderate to the extent that the reputation of the institution he serves is liable to suffer is simply fantastic. The article will, however, have served a useful purpose if it leads to a more sympathetic study of the problem of the young resident. The house surgeon—we include under the term any resident in the institution—by his training, his contact with suffering and the intimate human problems of sickness is usually years in advance of his peers in other realms of activity. In the early twenties he is called upon to shoulder responsibilities and make vital decisions, the parallel of which it is difficult to find in other walks of life. Indeed they are only to be discovered in such callings as that of the young airman pilot, but here the judgments needed are those of rapidity of thought and action, the quick estimate of distance and movement; they are not the decisions which come from long mental deliberation, and the careful sifting of evidence, the true province of the mature intellect. Yet this is what we call upon our youthful house surgeons to do, and any unbiased critic must admit that they acquit themselves with credit. In any body of men there must of necessity be some who lack the tact which is required in dealing with sick persons and their distracted relatives, whose sense of values is often disturbed by the strain to which they are subjected. Yet the average house surgeon realises their disability, and adjusts his conduct to it in a manner which often fills his elders with admiration. "Juno's" criticism reflects not so much indeed upon the character of the average house surgeon as upon the election committee of the institution which is so unhappy in its choice among the ranks of applicants. She complains of trouble that has arisen through negligence or lack of knowledge of the legal responsibilities of a house surgeon, instancing the notification of infectious diseases and other aspects of medical law, and advocates a test of knowledge in regard to these matters before appointment. Now every doctor receives such instruction before qualification, but it would be simple for any institution to call the attention of its officers, say by a small printed pamphlet, to legal obligations, the neglect of which is liable to cause unnecessary work and perhaps friction with the local authorities. Liberality in thought and action is a natural and desirable attribute of youth, but waste would undoubtedly be diminished by soliciting the collaboration of hospital residents who do not, we feel sure, suffer from the instinctive lack of sympathy and the unhelpful attitude to the general working of the institution with which they are credited. No body of young men work under such circumstances of stress and strain, night and day, for very meagre immediate (or financial) reward, with such loyalty and devotion and efficiency as do the residents of a hospital. Owing to economic factors, and the voluntary system, much of the most responsible and onerous work of hospitals is carried out by newly qualified men and women on the threshold of life. Some of it could be done more tactfully, no doubt, by men of long experience and mature judgment, but such labour costs money, which hospital boards refuse to pay. They now get much of their skilled work done at an absurdly low cost, by an army of young and enthusiastic men, who are learning to add to the knowledge acquired in their academic career the wisdom accumulated through daily contact with sick people, their relatives and attendants. This is the system which, as Mr. Percival Mills pointed out recently,[1] results in the general practitioner being the all-round man he is. It is typically British to give the house surgeon a degree of responsibility which, in a foreign clinic, would only be held by a man of many years' experience. In general, as Mr. Mills said, he responds to this trust extremely well.

THE MEDICAL PROFESSION AND THE MINISTER OF HEALTH.

THE Minister of Health, Mr. Arthur Greenwood, informs us that he proposes to enlarge the very wide range of the various forms of consultation which already subsist between the Minister and the medical profession. This extension of contact between the Government and medical opinion takes shape in the appointment, in a purely personal capacity, of Sir John Rose Bradford, Lord Moynihan of Leeds, Lord Dawson of Penn, and Dr. H. B. Brackenbury, as a small informal committee to confer from time to time with Sir George Newman, the Chief Medical Officer of the Ministry of Health. The object of the conferences will be to give ample opportunity for the committee to place before the Minister their views on any current medical matters about which they desire him to be specially informed, and for the Minister to consult the committee with the same ease.

Mr. Greenwood hopes to find in this arrangement a ready means of communication between the committee and himself as occasion arises, believing that it will contribute to the close, continuous, and sympathetic association which he desires to see maintained between the medical profession and the Minister.

THE LEGAL ASPECTS OF MEDICINE AND DENTISTRY.

A THESIS approved for the degree of doctor of laws in the University of London, recently published in book form,[2] combines considerable research into ancient history with a clear account of the statutes and case law, including the most recent decisions affecting the practice of medicine, dentistry, and veterinary surgery. Treating three cognate professions comparatively, Mr. Bullock is able to underline the differences in the latitude allowed by each to the unqualified practitioner. He does not hesitate to criticise the law which, while conferring a professional monopoly on the registered dental surgeon, allows any unqualified person to treat cancer, epilepsy, or paralysis, among other things. Considering the defects of the Medical Acts, he notices the weakness of the General Medical Council's control over the prospective medical student's preliminary educational tests and over the examining bodies' medical examinations; the Council maintains a register of medical students but cannot compel registration. The conflicting decisions under Section 40 of the Act of 1858 (recently invoked in the proceedings against Lieut.-Colonel Kynaston) are discussed, and a chapter on the law of professional negligence ends in an excellent exposition of the unprotected state of medical practitioners called upon to examine patients under the Lunacy Act machinery. Mr. Bullock is not concerned to deal specially with professional etiquette or to advise upon the day-to-day difficulties encountered by general practitioners. He has approached the subject rather from the legal side, to which his thesis provides a sound and faithful guide.

ÆTIOLOGY OF WHOOPING-COUGH.

THE article by Dr. Sugare and Prof. McLeod which appears on p. 165 of our present issue is a timely reminder how little we know of the causative agent of a prevalent and often devastating disease. Since Bordet and Gengou announced the discovery of *Bacillus pertussis* in 1906, opinion has fluctuated about the exact identity of the organism and its precise relationship to the disease. The actual association with whooping-cough was demonstrated by its discoverers, but subsequent workers have been unable to confirm this, neither have serological studies been of assistance, except, perhaps, to throw doubt on the view that *B. pertussis* is the incitant of whooping-cough. Prof. Bordet's contention is, we understand, that the failure of other workers to confirm his work depends on their not using the correct medium, and that if they were to do so the isolation of *B. pertussis* would present no difficulties. This view is now confirmed by the work done in the Leeds laboratory, in which the bacillus of Bordet and Gengou was isolated in 12 out of 21 cases. Moreover, Sugare and McLeod are able to show that *B. pertussis* is culturally different from *B. influenzæ*, can survive cold much longer, and gives a strong oxidase reaction. Interesting and instructive as these results are it remains to be proved that there is more than an association between this organism and the disease; and there is much to be done before Bordet's views can be accepted. Recent work at M.A.B. hospitals in London has shown a very small percentage of *B. pertussis*, and has failed to show any serological relationship of the organism to the disease. In France, however, Debré, Marie, and Prétet[1] have obtained cultures of *B. pertussis* by exposing plates of Bordet-Gengou medium, made with defibrinated horse blood, in front of the mouth of a patient towards the end of a paroxysm of coughing, and appear to have had no difficulty in isolating the organism after two to three days incubation at 37° C. It was shown by Krumwiede, Mishulow, and Oldenbush in 1923 that there were two types of the organism; serum made from type "B" only slightly agglutinated type "A," whereas type "A" serum agglutinated both organisms equally well. But Debré and his colleagues failed to find any type "A" organisms amongst their strains, whereas all their cultures of *B. pertussis* were agglutinated by type "B" serum. These results show that in Paris at least the strains of the Bordet-Gengou organism isolated from actual cases of whooping-cough were homologous. Leaving open the question of the exact role of *B. pertussis* in whooping-cough, we gather from the work here cited that (1) *B. pertussis* is found in a good proportion of whooping-cough cases; (2) that this organism is distinguishable biologically from *B. influenzæ*; (3) that in Paris all strains isolated were homologous. These results, if meagre, should help to clarify our knowledge of the ætiology of whooping-cough.

THE LONDON LOCK HOSPITAL.

A QUESTION asked in the House of Commons on July 22nd elicited the definite statement that the Minister of Health does not propose to publish the reports of the committee of inquiry into the management, administration, and staffing at the London Lock Hospital. The public is asked to be content with the assurance that the drastic revision of the laws and rules of the institution which, according to the Majority Report signed by Sir John Eldon Bankes and Dr. John Fawcett, is imperatively needed, is being made. The new laws passed by the govenors of the hospital on June 6th are not set out in detail in the letter to the Minister of Health from the Board of Management of the hospital, which is included in the incomplete documents now presented to Parliament.[1] The essential administrative changes made appear to be the inclusion of a number of women (amounting to one-third) on an enlarged Board, and the appointment of House and Finance committees with definite duties. The House committee will be responsible for the general supervision of the institution and for constant and regular visitation. The position of women acting on the honorary staff is to be officially recognised, the duties of the registrars defined, and the matron is to have a proper status and free access to the Board. The recommendation that each ward should have a fully trained sister in charge, to be relieved when off duty by a fully trained staff nurse, is met by the statement that each *floor* has a fully trained sister in charge, but that though the Board has tried continuously during the last few months to obtain the services of fully trained nurses, it has not yet been possible to fill all the posts. Meanwhile, the salaries of the nursing staff have been augmented by 10 per cent. and the hours off duty increased. The recommendations in the Minority Report, signed by Mrs. H. J. Tennant, suggest strongly that the amenities hitherto offered to patients in the way of privacy, accommodation, and washing facilities are inadequate for modern requirements. Mrs. Tennant expresses the hope that the adoption of her proposals, which are quite explicit, would entitle the hospital again to be recognised by the London County Council and the Ministry of Health. It will be remembered that the L.C.C. grant to the hospital ceased on March 31st, 1928, so that whereas in 1926 the hospital received the sum of £12,000 from this source, and in 1927 the sum of £10,000, in 1928 the grant was only £2300, and this year so far has been nil. The restoration of the grant would do much towards the re-establishment of public confidence, but the publication in full of both reports would, in our view, do even more. Mr. Neville Chamberlain held (see THE LANCET, 1929, i., 953) that the stipulation of the Board for a *private* inquiry would in any case preclude publication of the evidence taken; but even this difficulty could be surmounted by the goodwill of all parties concerned. Names of individuals mentioned could be withheld, if this were considered desirable. Since vigorous action has been taken to remedy many of the defects in administration which have been disclosed, the decision to withhold the full story need not be criticised on grounds of public policy. But a voluntary hospital, competing with other institutions for support from the charitable public, can only succeed against its rival claimants if enthusiasm can be kindled by reports of the work it is doing and the way it is doing it. Such enthusiasm is not damped by frank exposure of old-fashioned or inadequate organisation, but it is incompatible with a state of uncertainty of the degree to which an institution has been found wanting. The shadow of distrust cast by reflections on internal and domestic management is not cleared by assertions that reforms are being instituted. But in our view distrust would not long survive the publication in full of the reasons which moved the Board of Management to demand an inquiry and of the evidence on which the reports of an impartial committee were based, especially as the documents already available give ample guarantee of the zeal with which a complete reorganisation is being pursued.

FROM a field of 150 applicants Dr. J. A. Brincker, Dr. W. Brander, and Dr. W. A. Daley have been chosen to fill the three posts of principal medical officer of the divisions in which the public health department of the London County Council is being organised. Dr. Brincker, who will take charge of the division concerned with infectious diseases, is promoted after many years' service in the department. Dr. Brander, formerly medical superintendent of the hospital belonging to the Hackney Guardians, will take charge of poor-law medical administration, while Dr. Allen Daley, medical officer of health and school medical officer of Kingston-upon-Hull, comes south to take over general public health administration, including housing and school medical service. Ninety-three candidates applied for the post of matron-in-chief to supervise the nursing staff at the hospitals transferred to the Council. From these Miss D. E. Bannon, formerly matron of St. Mary's Hospital, Paddington, has been selected.

Public Health Services.

DEATHS FOLLOWING VACCINATION.

AT the resumed inquest at Stepney on a girl of five, who died on July 11th, it was stated by the medical officer of Mile End Hospital that the child was convalescing from pneumonia when, two days before the time appointed for discharge, another child in the same ward came out with a small-pox rash and all the contacts were vaccinated, so far as the parents' consent could be obtained. Vaccination was done with Government lymph on June 25th; on July 9th the child's temperature rose to 100° F., after being very excitable on the previous evening; drowsiness and headache followed, with increasing stupor ending fatally on the 11th. One other child was vaccinated with the same lymph. Dr. D. L. Thomas, medical officer of health for Stepney, said that this was the first case of encephalitis following vaccination reported in the borough. During the present year 285 cases of small-pox had been reported with two deaths, and 10,000 vaccinations had been done by public vaccinators. Mr. R. L. Guthrie, the Coroner, recorded a verdict of death by misadventure, adding that there was a certain risk from vaccination which doctors did not recognise until recently.

A boy of 12, whose father had objected to his vaccination in infancy, was vaccinated on July 3rd, since this was a condition of his participation in a holiday. His arm was in a satisfactory condition when examined a week later. On July 17th he became drowsy; he was taken to Poplar Hospital on July 18th and did not recover consciousness before he died. The inquest opened by the East London coroner on July 22nd was adjourned until July 29th for further medical evidence.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED JULY 13TH, 1929.

Notifications.—The following cases of infectious diseases were notified during the week:—Small-pox 115 (last week 153); scarlet fever, 1071; diphtheria, 1012; enteric fever, 58; pneumonia, 912; puerperal fever, 40; puerperal pyrexia, 80; cerebro-spinal fever, 13; acute poliomyelitis, 8; acute polio-encephalitis, 2; encephalitis lethargica, 20; dysentery, 16; ophthalmia neonatorum, 145. No case of cholera, plague, or typhus fever was notified during the week.

---

[1] Papers as to the Administration of the London Lock Hospital and Home. London: H.M. Stationery Office, 1929. Cmd. 3363. 3d.

The number of cases in the Infectious Hospitals of the Metropolitan Asylums Board on July 16th–17th was as follows:—Small-pox, 198 under treatment, 11 under observation (last week 209 and 6 respectively); scarlet fever, 1364; diphtheria, 1652; enteric fever, 10; measles, 201; whooping-cough, 410; puerperal fever, 29 (plus 11 babies); encephalitis lethargica, 125; "other diseases," 30. At St. Margaret's Hospital there were 18 babies (plus 11 mothers) with ophthalmia neonatorum.

Deaths.—In the aggregate of great towns, including London, there were 2 deaths from small-pox, 1 (0) from enteric fever, 37 (6) from measles, 4 (2) from scarlet fever, 27 (7) from whooping-cough, 22 (8) from diphtheria, 32 (8) from diarrhœa and enteritis under two years, and 27 (3) from influenza. The figures in parentheses are those for London itself.

The two deaths provisionally classified to small-pox were assigned to Stepney and Willesden. Liverpool reported 4 deaths from measles; Bootle, Bradford, and Tynemouth each 3. Liverpool also reported 3 deaths from whooping-cough; Bradford 3 from diphtheria. The highest figure for deaths from diarrhœa comes from Birmingham, 5; Liverpool following with 4, and Leeds with 3.

The number of stillbirths reported during the week was 281 (corresponding to a rate of 40 per thousand births), including 40 in London.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

CCXCVI.—THE TREATMENT OF STERILITY IN WOMEN.

PART II.—LOCAL MEASURES.[1]

THE methods of examination discussed last week may show some generalised condition of the pelvic tract, a general under-development or inflammation, or a gross lesion such as multiple fibroids with chronic inflammatory degeneration of the tubes and ovaries. One or more of the following conditions may call for treatment.

Intact or Painful Hymen.

Quite apart from vaginismus, the amount of obstruction caused by the hymen is relative and has to be treated on this basis. Comfort and confidence must be assured to the patient. In dealing with minor trouble the passage of vaginal dilators may be sufficient, but in my experience it is usually worth the patient's while to undergo operative measures under anæsthesia. The hymen is incised to its base in the mid-line posteriorly and the tips of two fingers of the left hand introduced to stretch the orifice to the required extent, the musculature at the base of the hymen being nipped meanwhile until sufficient room is obtained. The remains of the hymen are then removed, and the diamond-shaped space produced by the incision is sutured from its upper to its lower limit. Sometimes a large vaginal dilator is left in situ for some hours. The patient need not be kept in bed for more than two or three days. At the end of a fortnight a very important part of the treatment is performed. A series of vaginal dilators is passed not so much to dilate the parts as to prove to the patient what can be achieved without pain.

Vaginal causes of sterility are comparatively infrequent. Malformations and narrowings occur, and must be treated when they are considered to be factors in the prevention of conception.

Malposition or Abnormality of the Cervix.

The position and health of the cervix are of the first importance. If, as already indicated, the spermatic fluid is deposited elsewhere than on the cervix, its rapid deterioration, due to the acid reaction of the vagina, is assured. Malposition of the cervix occurs most frequently in association with retroflexion, when its position is always forward. The condition of retroflexion of the uterus may be directly associated with a further cause for sterility, kinking of the tubes, and tends to be associated with their further degeneration. Retroflexion is a frequent cause of secondary sterility. When a retroflexion appears to be the cause of sterility, if it is otherwise symptomless and the uterus and appendages are free from any suspicion of adhesions, the simplest treatment, well worth while before operative measures are suggested, is readjustment of the position with a sound and the insertion of a Hodge pessary. This can be done in many cases without anæsthesia. It is best to introduce the sound, with the help of speculum and volsellum, while the patient lies on her back, manipulate the uterus into its right position, and then turn the patient into the knee-elbow position before removing the sound and introducing the pessary. Air pressure maintains the uterus in its new position until the Hodge is suitably placed. The pessary can remain in situ for three to four months without douching, and must be retained for three to four months after pregnancy has occurred. I have no faith in the method often practised of "pushing up" the uterus or adjusting it bimanually without anæsthesia and without a pessary, as giving anything but the most temporary relief. I have, however, known the uterus to retain an improved position after such treatment long enough for pregnancy to occur.

If the uterus is fixed in retroflexion (in which case there are adhesions also of the tubes and ovaries), or persists in falling back in spite of the support given by a Hodge pessary, abdominal operation must be resorted to. It is not always easy to be sure whether or not a uterus is fixed. If adhesions are of old standing there may be no tenderness, though movement of the cervix from side to side usually elicits pain; on the other hand, the retroflexed body without adhesions may be very sensitive from congestion.

Acute anteflexion also results in a bad position of the cervix. It lies forward and points forward and is often poorly developed. Dilatation is indicated with the use of a uterine stem, which should allow of drainage, for a few days. These cases are less satisfactory to treat than are retroflexions. A long, pointed cervix may need dilatation and partial amputation.

A normal cervix with pin-hole os may need dilatation. Apart from this, the operation of dilatation of the cervix with or without curettage, according to the condition of the uterine body, gives good results in many cases for no obvious reason. The opportunity should always be taken to test the patency of the tubes under the same anæsthetic. If curettage is considered necessary, it should be done after the insufflation. Further, the cervix may have been pushed completely out of place by pelvic tumours or dragged out of place by scarring from old tears.

Any lesion involving the health of the cervix must be dealt with. Cervicitis may be present, following infection by gonococcus or other septic cocci, or lacerations may be associated with erosion. It is true that pregnancy may occur in spite of such lesions, but any lesion that interferes with the normal alkaline reaction of the cervical canal or alters the normal mucous secretion to pus is a definite obstacle to penetration of spermatozoa into the uterus. The fact that the methods of treatment advocated for cervicitis and erosions are so numerous is an index of the difficulty of curing these conditions. For success are needed patience, persistence and variation of the methods adopted, rest if possible in the early stages of treatment, and security from risk of further infection.

Uterine Body.—Inflammatory changes in the mucosa and fibroids of the submucous type are potent causes of sterility. Given normal tubes, myomectomy may give positive results, sometimes even when the uterus is considerably distorted by the operation.

---

[1] Part I. appeared last week.

Blockage of the Fallopian Tubes.

Treatment of the tubes is of value, varying with the site of the lesion. If there is blockage of the fimbriated extremity, which can be released, the prognosis is good. Hence, from the point of view of sterility, in all acute inflammations of the tubes it is important to operate as soon as possible after the temperature has finally settled at normal. Then one finds the tubes closed by adhesions, easily separable, to the *back of the broad ligament or the pouch of Douglas.* One or both tubes can often be saved by separating them carefully, opening up the fimbriæ, milking out the pus, and lifting the tubes with the uterus, which often needs suspension. I have been astonished at the number of patients who have become pregnant after such treatment. If an artificial opening must be made in a tube permanently blocked at the fimbriated extremity, it is important to evert the edges, exposing as little raw surface as possible, and leaving a strand of catgut through the new opening. There is reasonable hope of pregnancy ensuing in these cases. Where obstruction exists at the uterine end of the tube the prognosis is bad, though some surgeons have achieved success even here.

Ovarian Dysfunction.

Ovarian function is manifold and by no means completely understood. Where gross lesions exist, associated with sterility, their surgical treatment has sometimes resulted in pregnancy. When under-development is suspected, from evidence of irregular, infrequent, and scanty menstruation or adiposity, gland products containing thyroid, anterior pituitary and ovarian substance are indicated, although it is very doubtful whether the two last-named extracts have any action unless they are injected hypodermically. Injections of the female sex hormone, prepared commercially from the placenta and standardised as "œstrogen" are under trial. The great objection to this line of treatment is the number of intramuscular injections which have to be given to produce results. Small doses of X rays to the ovaries have given good results. The average dosage is 10 per cent. of the skin erythema dose, and is usually repeated two or three times. Menstruation has appeared where amenorrhœa existed, increased frequency and loss in cases of oligo-menorrhœa, each being followed by pregnancy after a short interval.

Treatment by Artificial Insemination.

This is only indicated or likely to give good results when there is impotence on the side of the male partner, his semen being healthy, and when the wife is normal. It may also be tried with hope of success in those cases where, the husband being normal, repeated post-coital examination shows no living spermatozoa on the cervix. It is important to choose the time of greatest fertility, to obtain a condom specimen under conditions as normal as possible, to retain the temperature of the specimen, *and to inject as soon after emission as possible.* In cases of impotence injection on to the cervix may be sufficient; otherwise a few drops of semen should be injected at low pressure into the uterine cavity. In any case, it is likely that repeated injections will have to be made.

Conclusion.

There still remain numbers of sterile marriages, where no treatment can be defined with confidence because the cause is so obscure. If a full investigation has been made, the cervix has already been dilated in association with insufflation. Attention should be paid to the general health of both man and wife, and advice given on change of scene, temporary abstinence, or any other detail suggested by the history of the individual case.

FRANCES M. HUXLEY, M.D., Ch.B. Manch.,
Surgeon to the South London Hospital
for Women.

Special Articles.

PHYSIOLOGY—THE BASIS OF TREATMENT.*

BY PROF. W. E. DIXON, F.R.S.

The Omission of Treatment from Text-books of Medicine.

WHEN the sciences of physiology and pathology a century ago passed from the realms of natural history to deduction and experiment, they naturally attracted the more original and eager minds in medicines, and the text of the writings of the nineteenth century deals with changes in structure and function. Treatment became neglected, the old shibboleths and rituals of treatment which had held sway for centuries were discarded, and there was nothing with which to replace them.

In the middle of the last century S. Skoda and K. Rokitansky (in Austria) perfected a system of physical diagnosis which has had a practical bearing on medicine ever since. Skoda made many experiments with drugs on the patient without any expectation of producing benefit; the patients were not improved and Skoda thought it mattered little how the patient was treated. It is right to say, however, that these experiments were deficient in many respects according to modern views. At this period the Vienna School held a prominent position in scientific medicine and the new doctrine rapidly spread. The physician studied disease in the patient: its beginnings, its progress, its effects, and the scars it left, as shown at autopsy. Scientific medicine looked askance at treatment; text-books spent many pages in describing the symptoms, diagnosis, and pathology of disease, but two or three lines dismissed the treatment; and even in our times the "scientific" physician is apt to be a diagnostician rather than a healer. The study of disease as an entity was the object aimed at, and a complete case was one which went to autopsy. *That most admirable and popular text-book* of medicine by the late Sir William Osler was typical of the text-books of the time. Dr. Simon Flexner once told me that Osler's book, characterised by its almost complete lack of indications for treatment, was largely responsible for the Rockefeller millions given to medicine. The text-books of the period told with considerable precision what was happening in the body during disease and what was likely to happen, but little or nothing on prevention.

This state of affairs was unavoidable; there was no specific treatment, there was no science of treatment, *for such a science could only come into existence* when physiology and pathology had reached some degree of precision. Diagnosis was then and is now far ahead of treatment; diagnosis is often accurate where there is no satisfactory treatment and yet diagnosis is only a means to the end.

[Prof. Dixon explained that the science of pharmacology was comparatively new, being the climax of physiology and pathology devised to subserve a practical end. He gave his reasons for depreciating the study of physiology only from the aspect of chemistry and physics. He said:—]

The Deflection of Physiology from Medicine.

I am by no means averse from the vast amount of academic research on these lines which is published annually, often by workers with little biological knowledge or training, but it surely should not precede the more immediate practical aspects of the subject. The modern attitude is expressed by a distinguished young biochemist who, in reviewing a well-known book on chemotherapy in 1928, asks "Might not the time and resources spent on chemotherapeutic research be diverted more profitably to the study of chemical and physical mechanism?" The same attitude is reflected in the awards of Fellowships and Scholarships for Medical Research. Formerly all the recipients were primarily biologists with a medical training: now a medico-biological training is unusual. Physiology in the broad sense in which it was used by Claude Bernard and Huxley has given place to a new physiology of physicochemical reactions: I might go beyond this and say that physiology is getting further and further from practical medicine, and this is the more regrettable as most of the Chairs in Physiology are connected with the Medical Schools and because the science of treatment is largely dependent on experimental physiology. Prof. J. S. Haldane clearly had this in mind in 1923 when he wrote: "We may say without serious misrepresentation that the official present-day view of physiologists is that physiology . . . aims at investigating the physics and chemistry of life, and might properly be called biophysics and biochemistry."

---

* Part of the Presidential Address delivered to the Section of Physiology of the British Association for the Advancement of Science at Capetown on July 24th.

[Prof. Dixon deplored the fact that biology had lost ground as an educational subject in the last twenty years, and urged that renewed attention should be paid to this science and also to pharmacology. He proceeded :—]

The Neglect of Pharmacology.

No branch of experimental biology has received less consideration in Great Britain than that of pharmacology; it is also the most neglected branch of medicine. And although the object of medicine is the healing of the sick, it is amazing that medical schools in Britain, often equipped with all other modern laboratories, lack departments of therapeutics. I was once asked at a meeting, by a leading medical man, what has pharmacology ever done? The answer is, of course, that it has formulated and brought reason and knowledge into treatment of the sick; so much did it impress that great pathologist, Ehrlich, that he left his sera and turned his attention to drugs, and with the unlimited resources at his disposal gave the world, amongst other drugs, salvarsan: so much did it impress the brilliant French chemist, Mr. Fourneau, that he has confined his studies to those of drugs, a study which has resulted in the synthesis of many valuable arsenical compounds and dyes. In America many centres, including the Rockefeller Institute, have turned to the study of drugs; and Italian pharmacology is doing the same.

Stereotyped Prescriptions.

I have heard it said by a leading official of our Ministry of Health, speaking to panel practitioners, that they, in the Ministry, do not want stereotyped prescribing in treatment. Surely there was never such nonsense. If there is a best treatment, let us have it whether it is stereotyped or not. In this respect the British Medical Association has given the profession a lead and shown by the experience of a great number of doctors that there is a best way of treating varicose ulcer in which the patient gets well quicker than by other ways, an advantage both to the patient and to the community who have to keep him whilst he is unfit for work.

Separate Physicians for Diagnosis and for Treatment.

The British physician is a skilled diagnostician and is in the forefront in all that pertains to this subject. The literature is so extensive that it is impossible for the average clinician to do more than this. But how few of them do, or perhaps the more correct word is "can," occupy the same time in the study of recent advances in general therapeutics? The successful physician has, generally speaking, to be content with such references to treatment as are to be found in clinical reading. The general physician must always be a necessity for diagnosis; but the details of treatment of patients will, I believe, in the future be handed over to those who have made a special study of the treatment of that particular group of diseases from one of which the patient is suffering. This is already the position in tuberculosis.

Experimental Methods in Therapeutics.

But the advent of institutions for experimental therapeutics is upon us, though Britain has taken little part in the movement. In this connexion we welcome the magnificent buildings of the University of Capetown, and when the new hospital with its medical school is completed I confidently anticipate that adequate accommodation will be provided for that important branch of applied physiology, pharmacology, and that this will include laboratories of physiology and organic chemistry, which must be in close and direct association with the wards. The enormous importance of one branch of treatment to Africa, chemotherapy, I will refer to later. From what has been said, it is not surprising that British pharmacology should be so much behind that of other countries in the production of new curative remedies; practically all come from abroad; I may mention ephedrine for spasmodic asthma, liver extract for pernicious anæmia, insulin, the organic arsenicals, the dyes such as 205, the new anæsthetics local and general, hypnotics, and many others.

Fallacies in Experiments on Healthy Men.

It has been often stated that the action of remedies may be best determined by experimenting with them on healthy men. This is not true; quinine is used to treat malaria, yet not one of the subjective symptoms induced in man has the remotest connexion with its curative properties. The same is true of the use of the iodides in syphilis and salicylates in rheumatism. The experiments of Joig and his pupils in 1825 with camphor, digitalis, and other drugs on healthy men added nothing of value to pharmacology. Subjective sensations are, it is true, produced which are erroneously attributed to the drug which has been taken. The late Dr. Rivers and myself were nearly the dupes of such an experiment which I will give in full because it illustrates the imaginary sensations and effects produced by S. Hahnemann and his pupils, by Perkin with his retractors, and by more modern physicians with their mystic apparatus.

Our experiments were made on healthy men under a regular régime as regarded sleep, exercise, and diet. The men were practised with the use of the ergograph during several weeks at the same hour daily, until their output of work was constant. We found that the administration of a dose of caffeine dissolved in water one hour before the experiment greatly increased the output of work for that day. This was repeated on several occasions, always with the same result, and we naturally regarded the effect as due to the caffeine. This, however, was not the case: the effect was due to the ritual of taking a drug; the drug day assumed an enhanced importance in the mind of the operator and the mental effect sometimes referred to as suggestion was principally responsible. We had no difficulty in showing that water made bitter with a trace of quassia or other simple bitter had a similar effect.

Few, if any, experiments made on man without the most careful controls are of any real value. Properly controlled experiments have been made, however, with many substances. Precise experiments, for example, have been made both in Germany and America with bromides in epilepsy. In these experiments half the epileptics were given potassium chloride and the other half sodium bromide; after several weeks' use the bromide had decreased the number of attacks, whilst the chloride had no distinct action.

[Prof. Dixon discussed the applications of chemotherapy in parasitic diseases and described recent preparations of the ductless glands in disorders of the endocrine system. He then spoke of civilisation as leading to an exaggerated nervous sensibility, which was a much commoner feature in those engaged in a mental indoor life than in those engaged in an outdoor physical life. He drew attention to the effect of tobacco in diminishing nervous sensibility and to the circumstance that though beer was a soothing beverage, and caffeine was a stimulating one, it was the supersensitive people who drunk caffeine and not beer in excess. It seemed to him not unlikely that this substitution of tea for beer was not wholly unconnected with the tendency of highly civilised nations to become supersensitive and neurotic, for this was the groundwork upon which drug addiction was built. He concluded :—]

I have endeavoured to show that all precise knowledge in therapeutics is based upon controlled experiments on animals or man, and that the elucidation of the action of medicaments by the methods and data of experimental physiology is one of the most important steps taken to place medicine on a scientific basis. How important this is may be gauged from the fact that all fundamental advances in treatment in the last 30 years have originated directly or indirectly from experiments on animals. There can be no doubt then that the future of therapeutics, and therefore of medicine as a whole, is intimately connected with physiology; there can be no doubt that advance in the practice of medicine is dependent on those trained in the methods and fundamental truths of physiology, who devote themselves in the ward and biological laboratory to investigating how best to prevent or cure disease and so relieve suffering. Britain for 50 years has every reason to be proud of her progress and achievements in physiology; it is acknowledged that she can show records second to none and that her savants have included some of the world's greatest investigators. It remains for us to hope that in the future she may attain equal success in the associated sciences directly concerned with the relief of suffering and cure of disease.

MENTAL HOSPITALS ASSOCIATION.

THE eleventh annual meeting of this Association was held on July 17th, with Alderman Sir WILLIAM HODGSON (Cheshire) in the chair. The Chairman, in the course of his address, referred to the difficulty of suggesting new legislation at a time of political crisis, but declared that the problems of lunacy and mental deficiency were above party and truly national. Some of the suggestions of the Royal Commission might be taken as sure of general acceptance and would supply urgent needs. He referred to the paramount importance of treatment for incipient mental disorder without certification, and suggested that a conference of local authorities should be called to consider the greatly overdue Lunacy Bill, which would meet with general support if formed on enabling rather than compulsory lines. It was most desirable that the Government should realise that the spirit of local government must be protected from excessive arbitrary interference by central officials. The Association's advance in strength and influence had been based upon steady insistence on efforts to gather information and on the absence of any interference with the absolute autonomy of visiting committees. Organisation for mutual helpfulness was the keynote of their work, which was too humanitarian for isolation or personal or political preference.

The first business on the agenda was an expression of regret that another year had passed without legislation to reform the lunacy laws. The Committee hoped to see a Bill introduced very soon, and the meeting cordially endorsed this hope.

The Committee drew attention to the serious shortage of accommodation and the prohibitive cost of building. Councillor W. M. CLARK (Durham) said that Durham had saved £3000 on an outside estimate by utilising material and labour available within the institution, but Councillor HOPKIN (Nottingham) pointed out the objections which the trades-unions would raise if this plan were widely followed. He thought there was no hope of obtaining the required accommodation in reconstituted poor-law hospitals, because the institutions were needed for old age pensioners unable to live at home on their pensions. If they could be helped to live outside, the beds they occupied might become available for mental cases. Alderman E. H. MOLE (Glamorgan) pointed out that this might be true in industrial areas, but agreed with Alderman R. BRUFORD that the problem of accommodation in other areas would solve itself when one authority was responsible both for poor-law and mental hospital work.

The Mental Nurses' Examination.

This vexed problem again came up for consideration, and an acute difference of opinion became manifest. For thirty years the examination and certification of mental nurses was in the hands of the Medico-Psychological Association, and the syllabus was drawn up by medical superintendents with reference to the special needs of the work they control. With the incorporation of the General Nursing Council a difficult situation arose. As Dr. G. H. GRILLS expressed it in proposing a motion, the G.N.C. did not want the advice of medical superintendents, and would not have it, and in his opinion most medical superintendents found the syllabus proposed by the Council quite impracticable. His motion was:—

> That this meeting views with some apprehension the existing unsatisfactory conditions regarding the national registration of mental nurses, and urges the General Nursing Council for England and Wales to provide that the possession of the certificate of proficiency in mental nursing awarded by the Royal Medico-Psychological Association shall entitle the holder thereof to be registered, on payment of the fees, in the mental section of the register of nurses of the General Nursing Council.

He pleaded strongly the difficulty of sparing nurses from a mental hospital to go to a distant centre for examination, and of their finding the money for fares and lodgings, as well as the five-guinea fee, and declared that a first-year probationer trained on M.P.A. lines was more use in a mental hospital than a fully registered general nurse. She must acquire in her first year an elementary knowledge of mental nursing and of first-aid, or she was useless in the wards; the G.N.C. syllabus postponed these subjects to the final examination. It was impossible, he thought, to have a single portal of entry for every kind of special nurse. Not more than two mental hospitals in England and Wales made the G.N.C. examination compulsory, and soon there would not be a single registered nurse in the mental hospital service, which would be a serious situation.

On the other hand, Dr. J. I. RUSSELL (N. Riding, Yorks.) and Dr. J. F. FRANCIS (Leicester), supported by Dr. D. RICE (Norwich) and Dr. R. EAGER (Devon), took the attitude that the position must be accepted and some compromise found by the medical superintendents. The General Nursing Council, they argued, was a statutory body, and its formation had undoubtedly been a forward step. It had now decided finally that it would not delegate its powers to any voluntary body, and that it regarded control of examinations as a part of its duties. This being so, its examination was the legal one and must be accepted sooner or later, and the medical superintendents were, in a sense, deceiving their probationers by encouraging them to take another diploma and dismissing them if they did not. Dr. FRANCIS said his committee had recognised the inevitability of the situation, and had given up training for the M.P.A. certificate. The examination fee was repaid by the bonus given to the nurses who had passed the examination. He had found no insuperable difficulty in teaching the requisite special subjects during the first year while training probationers for the G.N.C. examination, or in sending the nurses to the examination centre. He suggested that the M.P.A. might organise a higher special examination, to be taken by mental nurses after registration. Finally, it was decided to refer the matter to the executive Committee for consideration and report.

Other matters briefly discussed included the degree of control of mental hospital finance which should be exercised by the local authority; the degree of control that should be exercised over minor items in the uniform dress of members of mental hospitals' staffs; the facilitation of removal of patients to mental hospitals near their homes or relatives; and the reduction of railway fares for relatives visiting patients in mental hospitals. Alderman R. BRUFORD (Somerset and Bath) was elected chairman, and

Alderman W. E. **Lovsey** (Birmingham) vice-chairman, and Alderman C. **Hornby** (Lancs) was reappointed hon. treasurer for the ensuing year. The Committee was re-elected, with the addition of the retiring chairman, of Miss **Briscoe** of Fulham, and of Councillor **George Hunt** of Leicester.

The Salaries of Medical Officers.

During the morning the meeting went into committee to discuss a memorandum on the salaries of whole-time medical officers, which was accepted and confirmed. This scale of salaries was the outcome of a conference held at the Ministry of Health between representatives of the County Councils Association, the Association of Municipal Corporations, the Urban District Councils Association, the Rural District Councils Association, the London County Council, the Association of Education Committees, the Mental Hospitals Association, the Metropolitan Boroughs standing joint committee, and the British Medical Association. Briefly, the annual salaries agreed upon are as follows:—

Officer	Minimum commencing salary	Annual increment	Maximum	Emoluments
Resident medical officers and assistant M.O.'s. in mental hospitals	£350	£25	£450	Board, lodging, laundry, and attendance
Medical officers with at least 3 years' post-graduate experience	£500	£25	£700	
Senior medical officers—i.e., those in charge of services or departments	£750–£1100†	£50 every 2nd year	£1100	
Medical superintendents (excluding mental hospitals)—i.e., institutions with more than 100 beds	£750–£1100‡		£1100	Included in salary
Medical officers of health*	£800–£1800‖			

* Assistant M.O.H.'s 60 per cent of this scale.
† According to responsibility and scope. ‡ An additional £50 for each 100 beds over 200. ‖ According to population.

After an office has been held at the maximum salary for four years, the employing authority is to consider whether the officer's remuneration should be increased beyond the maximum. The scale is not to apply to posts limited to a term of one year, or to officers without previous professional experience. There is to be no differentiation of salary on account of sex, and any intention to dismiss on marriage should be specifically stated in the advertisement. The memorandum mentions the desirability of providing married quarters for assistant medical officers in mental hospitals, and of allowing at least four weeks' annual leave. An additional £50 per annum is recommended for officers who hold the Diploma in Psychological Medicine. Only the first annual increment is to be allowed to officers who, in the opinion of their medical superintendent, do not take advantage of the opportunities offered them for obtaining the diploma. Temporary medical officers should not ordinarily be employed, the conference advised, for more than twelve months, and clinical assistants should not be appointed to undertake the duties of junior medical officers. An advisory committee is to be constituted to deal with any difficulties arising out of the working of this agreement, which is to come into force on April 1st, 1930, and to remain in force for five years, and thereafter from year to year, subject to one year's notice from any of the contracting parties. These recommendations meet, in practically every respect, the requirements of the British Medical Association, out of which the conference arose in the first place.

MEDICINE AND THE LAW.

Shewry v. Maybury.

The lengthy litigation in the case of Shewry *v.* Maybury has ended in a manner satisfactory neither to plaintiff nor defendant, and presumably satisfactory neither to judge nor jury. The special jury, it will be remembered, after a trial lasting a week, failed to agree on the question whether the condition of the infant (Leslie Shewry) was caused by Dr. Maybury's treatment. The jury had agreed in its answers to a string of other questions already summarised in these columns,[1] and on July 9th Dr. Maybury's counsel asked that judgment might be entered for him since the plaintiff had failed to establish his case. The point at this stage for the Lord Chief Justice to decide was not how he would himself have answered the question on which the jury disagreed. Had that been his duty, Lord Hewart would, he said, have answered in Dr. Maybury's favour. The point he had to decide was whether or not there had been evidence to go to the jury upon which the jury might have answered the question in the opposite way. Lord Hewart, therefore, reserved judgment in order to give himself the opportunity of carefully re-reading the whole of the evidence; eventually (on July 19th) he gave his considered decision. He decided that, notwithstanding his own personal view, he would not have been entitled at the original trial to rule that there was no case to go to the jury. He would not have been entitled to direct the jury to find a verdict for the defendant. "There was, I think, some evidence, including some medical evidence, which, if the jury were prevailed on to accept it, was sufficient to entitle them to answer affirmatively the question 'was the condition of this infant caused by the treatment administered by the defendant?' . . . It may well be that, in view of the intrinsic nature of that evidence, and of the contrast between it and the cogent evidence adduced on behalf of the defendant, such an answer would have excited legitimate surprise. But all such considerations appear to me to be quite irrelevant if, in fact, there was a conflict of evidence for the jury to determine. Here, I think, there was such a conflict, and the jury having disagreed, it is not possible for me to enter judgment."

The result is that, notwithstanding that the Lord Chief Justice has now on two occasions made known his opinion that on the merits of the evidence the verdict should be in favour of Dr. Maybury, the disagreement of the jury upon a fundamental question vitiates the patient trial before Lord Hewart and leaves the plaintiff at liberty to start his action afresh. If this latter course is taken, twelve laymen will once more be selected to decide a technical issue; plaintiff's counsel will once more seek to inflame their natural sympathies by a terrible story of a healthy baby subjected soon after birth to unnecessary and improper treatment resulting in incurable mental deficiency and epilepsy; expert witnesses will once more come forward to say that whatever a medical practitioner decided to do nine years ago was wrong though he saw the patient at the time and they did not; "cogent" evidence will be given again on Dr. Maybury's behalf that he was right, and finally the jury will be expected to reach the mediæval standard of unanimity in the face of a puzzling series of questions framed by the judge with an eye to possible legal arguments in the Court of Appeal. The death of the child is the only new fact to be considered upon a re-hearing, and, unless there is a post-mortem examination, this fact may be without significance. Nothing, it is agreed on all sides, could have been more lucid or impartial than the Lord Chief Justice's summing up. But, as he has himself explained in his judgment, a judge cannot be placed in the position of a jury; unless he found himself able to declare that a verdict by the jury against Dr. Maybury was impossible he cannot supply the deficiency which the jury's disagreement has caused. Comparison between the judicial faculties of judge and jury is otiose—on the one side a man expert in the knowledge and application of the law, familiar with previous actions depending upon allegations of negligence, and trained to weigh evidence and exclude irrelevancies; on the other side twelve casually chosen laymen who have none of such gifts. The Lord Chief Justice, it must be reiterated, has twice declared that, had he had the power, he would have decided in Dr. Maybury's favour; the jury has not been able to decide unanimously against Dr. Maybury. No recent case has so flagrantly exhibited the occasional discrepancy between a judge's and a jury's view of identical facts, or the disadvantage of leaving technical issues (affecting a defendant's professional reputation and livelihood) to a jury of laymen. It will stimulate and justify the demand for some other form of tribunal. The use of medical assessors would at least abbreviate the length of such a trial. In any case it would seem reasonable that there should be some form of protection for a medical practitioner against charges of negligence relating to treatment given as much as eight years ago.

SCOTLAND.

(FROM OUR OWN CORRESPONDENT.)

The Medical Curriculum.

ON Thursday, July 18th, the graduation proceedings took place in connexion with Edinburgh University; the ceremonies were held in the M'Ewan Hall, and Prof. J. T. Mackie, Professor of Bacteriology in the University, delivered an address to the new graduates in which he outlined the defaults of the system, of which they were the most recent victims. Once again the curriculum was indicted as over-loaded—in Prof. Mackie's eyes it "resembled a building originally compact, extended in the course of time by new storeys and annexes, always commodious, but tending to become somewhat rambling, and—worse still—top-heavy on its foundations." Accordingly he concludes that "the time has perhaps come when it should be razed to the ground, and rebuilt on a new plan." He followed this expression of policy, which must be regarded as summary when applied to the outcome of (say) seventy-five years of developments, by stating that, while the study of medicine might be regarded as that of a great branch of biology, so that medical workers might be expected to furnish the world with supreme biologists, the graduated approach between biological studies and the minutiæ of anatomy and physiology was wanting in the curriculum, which, in this place therefore was irrational. Is this a weakness in the curriculum which can be met by extension of time? Or can it be met by an alteration of the examinational system, by which certain subjects, or the developments of certain subjects, are relegated to post-graduate work? Or, without altering the time of the medical course proper, can pre-medical studies be framed so as to lighten subsequent studies, while being available for the mass of students? Prof. Mackie, in his comprehensive survey of medical education, did not ask precisely those questions, but they are the questions which have to be faced, and towards a reply he made the suggestion that, on the analogy of the honours degrees in other Faculties, the University graduate in medicine might be able to take a pass or an honours degree.

Cowan House, Edinburgh.

A further £20,000 has been presented to the University of Edinburgh by Mr. Thomas Cowan primarily for scholarships to promote the entry of students of small means as residents into Cowan House. This House, which is now nearing completion, is designed to be a social centre for male students of British extraction, and to attract as residents young men who, in respect of intellectual force or other personal characteristics, are likely to have a useful influence on their fellow-students and to become a credit to the University.

Since it is difficult to foresee how far the provision of scholarships may be necessary or desirable, Dr. Cowan is leaving the University full powers to apply the fund in any other way that will develop the usefulness of Cowan House.

Housing Conditions in Edinburgh.

Since the inauguration 30 years ago of a Sanitary Department in Edinburgh over 5000 uninhabitable houses have been closed. The housing policy of the Corporation is now making good progress in the abolition of the slums by means of improvement schemes and the re-housing of the occupiers in more congenial and hygienic surroundings. At the end of 1928, 1034 houses had been inspected under the Housing Regulations (Scotland) 1928, and of that number 971 were considered to be in a state so dangerous or injurious to health as to be unfit for human habitation. In connexion with 57 houses closing orders were made. A reduction in overcrowding was reported. In the last three years the number of cases of overcrowding brought to the notice of the Department has fallen from 1640 in 1926 to 1542 in 1927, and 1323 in 1928. In 140 cases the overcrowding was due to or aggravated by the keeping of lodgers or the sub-letting of rooms. In the one-apartment overcrowded houses as many as 8 to 11 persons were found in residence, and in the two-and three-apartment houses as many as 10, and in one case 19, persons were found.

Animal Diseases.

At the annual meeting of the Animal Diseases Research Association of Scotland, held at the Moredun Institute, Gilmerton, a year of progressive work was reported. The Association now possess a well-equipped Institute with facilities for all kinds of research, but the lack of trained observers is still felt; there is, for example, urgent need for a clinician on the staff of the Association. As lamb dysentery can now be controlled, its general nature being understood, it has been possible to cease intensive work on it and take up louping-ill and the braxy-like diseases of sheep. Grass sickness in horses is the outstanding unsolved problem in front of the Association; information concerning the disease has been collected and distributed to the numerous collaborators. A scheme for the investigation of bovine abortion disease is under the consideration of the Empire Marketing Board. Transmission experiments with scrapie are in hand, and Calmette and Guérin's tuberculosis vaccine is being used, although with due reserve about its value.

Tuberculosis in Fife.

Dr. Pratt Yule states that the mortality-rate from tuberculosis in the County of Fife in 1928 was less than half what it was in 1914, the present rate being 0·70 per 1000. Various factors are responsible for the lessening grip of tuberculosis on the community, but Dr. Yule regards as most important the steady campaign that has been waged against the disease since 1912. The Fife scheme differs from that usually accepted as necessary for the control of tuberculosis. Hitherto, dispensaries had not been established in the county, the patient being visited, examined, and supervised in his home. The mortality-rates compare favourably with those of other Scottish counties of like industrial characteristics.

New Scientific Institutions in Aberdeen.

The notable additions during the past year to the medical and scientific resources of Aberdeen were recorded by Sir George Adam Smith, Principal of the University, on Graduation Day. The new Hospital for Sick Children has been completed and opened. An Imperial Bureau is being founded in close connexion with the Rowett Institute for Research in Animal Nutrition, which is to be the centre for recording and classifying researches in progress on animal nutrition throughout the British Empire. The National Department of Scientific and Industrial Research is to open another laboratory in close connexion with the University departments of physiology and bacteriology, and the Scottish Department of Agriculture had arranged for the establishment in Aberdeen of an Institute of Soil Research to be named the MacAulay Research Institute. This Institute will be run by a committee of 11, representative of the University, of the three Scottish Colleges of Agriculture and of the Scottish Department of Agriculture. The capital expenditure will be met by Mr. MacAulay, an Aberdonian now resident in Canada, up to a maximum of £10,000.

The Services.

ROYAL NAVAL MEDICAL SERVICE.

Surg. Comdr. H. M. Langdale is placed on Retd. List with the rank of Surg. Capt.

The following appointments are notified:—Surg. Lt.-Comdr. N. B. de M. Greenstreet to *President*. Surg. Lt.-Comdrs. (D.) M. F. Hopson to *Rodney;* and W. E. A. Sampson to *Vivid*, for R.N. Barracks, Devonport; J. L. Jean to *Vernon;* E. C. Bevis to *Victory*, for R.M. Infirmary, Portsmouth; H. J. Luck to *Victory*, for R.N. Barracks, Portsmouth; L. M. Hughes to *Pembroke*, for R.N. Barracks, Chatham; and F. W. Watt to *Victory*, for R.N. Barracks, Portsmouth; Surg. Lt. A. J. Burden to *Cockshafer*. Surg. Lts. D. Duncan to *Cambrian;* and H. N. V. Barnes to *Vivid*, for R.N. Barracks, Devonport.

ROYAL NAVAL VOLUNTEER RESERVE.

Prob. Surg. Sub-Lt. V. S. Hughes-Davies to be Surg. Sub-Lt.

Prob. Surg. Lt. A. L. Gunn to be Surg. Lt.

The following appointments are notified:—Surg. Lts. T. C. Stevenson and G. A. C. White (D.) to *Victory*, for R.N. Hospital, Haslar, for training; Prob. Surg. Sub-Lt. F. W. Chippindale to *Victory*, for R.N. Hospital, Haslar, for training.

ROYAL ARMY MEDICAL CORPS.

Capt. I. F. MacKenzie, late R.A.M.C. Spec. Res., to be temp. Capt., and temporarily relinquishes the rank of Capt.

Lt. (on prob.) R. R. Leaning, from the secd. list, is restd. to the estabt.

Lt. D. A'Brook is secd. under the provisions of Art. 205, Royal Warrant for Pay and Promotion.

TERRITORIAL ARMY.

Lt.-Col. J. S. Y. Rogers having attained the age limit retires and retains his rank, with permission to wear the prescribed uniform.

Lts. F. W. Bury and A. Barr to be Capts.

Hon. 2nd Lt. B. Reid (late R.A.F.) to be Lt.

ROYAL AIR FORCE.

H. C. S. Pimblett is granted a short service commission as a Flying Officer for three years on the active list.

Flying Officer C. Crowley ceases to be seconded to the Manor House Hospital, Golders Green.

Flight Lt. J. Twohill is transferred to the Reserve, Class D ii.

DEATHS IN THE SERVICES.

Deputy Inspector-General Charles William Buchanan-Hamilton, R.N., retired, who died on July 13th, entered the Royal Navy as surgeon in 1878 and reached the rank of Fleet Surgeon in 1894. He served throughout the Egyptian War, 1882, as surgeon to the *Beacon*, and was present at the bombardment of Alexandria, the seizure of the Suez Canal, the occupation of Port Said, Suez, and Ismailia, and at the surrender of the Aboukir, Damietta, and Ghimileh Forts (Egyptian Medal, Alex. Clasp, Khedive's Bronze Star). He also served as surgeon with the Royal Marine Battalion in the Soudan Expedition of 1884, and was surgeon of the Royal Victoria Hospital, and of H.M. *Sphinx*, at Suakin, until the close of the campaign (Suakin Clasp). He was surgeon of the Naval Brigade in the Burmese War, 1885, and was attached to the Burma Field Force in the advance to Upper Burma, and in the Indian Marine ship, *Tigris*. He also took part in the occupation of Mandalay and deposition of King Theebaw, and in subsequent operations (India Medal, Burma, 1885–87, Clasp). Previous to his retirement with the rank of Deputy General of Hospitals and Fleets in 1907 he was fleet surgeon of Sheerness Gunnery School and Dockyard.

BRITISH MEDICAL ASSOCIATION.

ANNUAL MEETING IN MANCHESTER.

PROCEEDINGS OF THE REPRESENTATIVE BODY.

THE annual Representative Meeting of the British Medical Association opened in Manchester on July 19th with Dr. C. O. HAWTHORNE in the chair. The President-elect, Prof. A. H. BURGESS, introduced the President-designate for 1930-31, Prof. W. HARVEY SMITH, of Winnipeg, and a short address of welcome to Manchester was read by the Lord Mayor.

Part-payment by Hospital Patients.

Much of the first day was devoted to considering the Association's hospital policy, which the Chairman said would be for some years the most important business of the Representative Body.

In 1927 the Council was invited to prepare a special "middle-class hospital policy," but it has preferred the alternative of suggesting amendments calculated to bring the present "voluntary hospital policy" into line with the new requirements of the public. These amendments involve, first of all, a change in the classification of the patients, who have hitherto been placed in three groups: (1) those unable to contribute in any way; (2) "private patients" who pay for special accommodation and who arrange for treatment fees independently of the hospital; and (3) an intermediate group of "tariff patients" who directly or indirectly pay part or all the tariff charges of the hospital. On behalf of the Council, Sir RICHARD LUCE proposed that a distinct group of "aided patients" should be recognised. It was to be hoped, he said, that there would be a steady growth of the class who did not want charity and who paid the full cost of their keep in hospital, including fees for medical attendance. This class, to which it was suggested that the term "tariff patients" should henceforth be confined, included those for whom payment was made by public authorities, approved societies, employers of labour, insurance companies, or under contributory schemes. Meanwhile, however, there was undoubtedly a large body of people who were able to pay only part of the cost of maintenance and treatment, and the Council held that these should be placed in a definite category. Fees for medical attendance on such patients would be paid to the visiting staff according to what proportion of the full tariff was received by the hospital from the patient or on his behalf.

The proposal to recognise an "aided" class of this kind was vigorously opposed. Sir ROBERT BOLAM, for Newcastle-on-Tyne, argued that some 80 per cent. of the industrial population could pay 2*d.* or 3*d.* a week to contributory schemes and thus pay the full tariff scale. But they would never be brought to do so if they were given a chance of paying a little as and when they thought fit. To admit that this large proportion of the public could never be expected to pay its way was to vitiate the whole position from the start. Small contributions should certainly be accepted, but it should never be suggested that they were adequate.—Mr. BISHOP HARMAN did not approve of making categories or policies cover exceptions which were disadvantageous. It was better to have an ideal than to accept the present conditions under which perhaps the majority of patients would fall into the "aided" class.—Dr. J. C. MATTHEWS feared that this amendment of the hospital policy would lend colour to the theory that hospital staffs ought only to get fees for patients who were paying full tariff charges, and Dr. PETER MACDONALD said it would certainly put an obstacle in the way of arranging full contributory schemes at York.

Among other speakers some support was found for the proposal, and Sir RICHARD LUCE argued to the effect that it provided a stepping-stone between those who were purely objects of charity and those who paid for themselves. But the meeting, by a large majority, decided to send this part of the new policy back to the Council for further consideration.

Private Patients.

The Council's new suggestions about private patients were accepted with but little alteration. The Association's policy tentatively sets out a scale of incomes, rising to £300 a year, over which no one should be admitted to hospital on a tariff basis. Where special accommodation is available at a voluntary hospital, persons earning more than £300 may be admitted as private patients, but as in the case of tariff patients this is not to be done (except in emergency) without the recommendation of a practitioner. The policy now approved provides that when the special accommodation takes the form of private wards in a hospital which has both public and private wards in one building then:—

> (*a*) If the hospital has a resident medical officer or officers and also a visiting staff which is ordinarily responsible for the care of all patients in the public wards, the patient should be under the responsible care of a member of the visiting staff in association with his own private practitioner. The latter should have free access to the patient and should have such share of responsibility and treatment as may be agreed upon between him and the member of the visiting staff concerned. This does not apply where the governing body has made special arrangements permitting practitioners not on the staff to have responsible care of their own patients.
>
> (*b*) If the hospital has not such resident officers and/or visiting staff the patient should be admitted under the responsible care of a private practitioner and should be allowed, if necessary, to call in any consultant of his choice.
>
> (*c*) The fees payable by the patient may be determined either by a scale agreed between the medical staff and the board of management, or by private agreement between the medical attendant and the patient.

When, on the other hand, there is in connexion with a voluntary hospital a separate home or annexe exclusively for private patients, then the patient should be allowed to select any available medical practitioner as his attendant, though the latter may be required to show evidence of special knowledge or experience if these are likely to be needed. In the case of cottage hospitals it is recommended that membership of the medical staff should be open to all practitioners in the district and that the patient should have the right to be attended by his usual medical adviser, to whom he would be responsible for fees in the usual way.

Discussion of these proposals failed to reveal any significant cleft of opinion, though on one point, Dr. E. R. FOTHERGILL persuaded the meeting to take legal advice. What would be the position, he asked the Association's solicitor, if the governors of a hospital were sued because they allowed a doctor to maltreat a patient on their premises without previously satisfying themselves of his competence? Would they not be liable for damages?—The fact that the Representative Body has come to take a wry pride in Dr. Fothergill's pertinacity did not prevent it from enjoying Mr. OSWALD HEMPSON's forensic reply that in the particular circumstances under discussion the patient had himself assumed full responsibility when he called in the doctor.

Services of the Radiologist.

After accepting certain recommendations by the Council concerning the representation of the medical profession on the governing bodies of "separate hospitals or institutions for paying patients not connected with voluntary hospitals," the meeting settled down to consider a memorandum on radiological services. This has been prepared at the instance of the British Institute of Radiology and in the form now approved by the Representative Meeting is likely to be adopted as the policy of the Institute also. It provides, inter alia, that an agreed share of fees received by a hospital for radiological services, or an agreed honorarium, shall be placed at the disposal of the medical staff.

> A hospital may, on the advice of the visiting radiologist, arrange a schedule of modified charges for radiological services within a specified scale of income limits, and based upon an average of one half the fees commonly charged for similar private work in the district; but the schedule so arranged is not to be published or exhibited publicly.
>
> A hospital in a district where medical practitioners are privately practising radiology should not provide radiological services for patients able to pay private fees. Where there is no such practitioner the radiologist to the hospital may be allowed to see private patients at the hospital, receiving not less than two-thirds of the fees paid by them.
>
> "The normal approach to the radiologist," says the memorandum, "is through the medical officers of other departments of the hospital, but in exceptional circumstances cases may be referred direct to the radiologist by private practitioners . . . Fees for services to patients in pay beds should be paid to the visiting radiologist in each individual case according to the service rendered, less an agreed proportion to the hospital to meet costs."

The suggestion that in exceptional circumstances the private practitioner may send his cases direct to the radiologist did not pass unchallenged, and Dr. MACDONALD said it would be unwelcome to most members of the visiting staffs of hospitals.—Sir RICHARD LUCE explained that radiologists set great store by it, and it was accepted after Dr. H. B. BRACKENBURY had emphasised the exceptional nature of the circumstances to which it was intended to apply.

Hospitals and Private Practice.

A further appendix to the Council's report, consisting of a "model contributory scheme for hospital benefit" was also agreed to with minor emendations. Brighton argued that such schemes were being worked out for the benefit of hospitals to the detriment of specialist practice; because a private practitioner could not give the services required it did not necessarily mean that the patient should go straight to a hospital. But Dr. H. G. DAIN, whilst admitting that the whole profession would sympathise with this opinion, believed that arrangements for payment of private practitioners could not be embodied in a model contributory scheme for hospitals. And this view carried the day.

Another aspect of the hospital's encroachment on private practice was illustrated in a picturesque speech by Mr. F. C. PYBUS on industrial accident cases. After pointing out that the apparently generous contributions of industrial firms were not always as handsome as they seemed, in view of the services rendered, he remarked that these cases constituted an abuse of the medical staff as well as of the hospital funds. He had recently saved a firm £500 by restoring a patient who was about to be compensated to that extent. Why should such work be done for the many firms who dumped their accidents at the hospital doors, paying amounts which barely covered their keep, and leaving the rest to be made up, perhaps, by pulpit appeals? Why should not such cases be admitted to private wards so that the very expensive labour put into some of them could be recognised by suitable fees? "Going home footsore and weary from my hospital after having saved a few lives and a few limbs," said Mr. Pybus, "I contrasted my position with that of the officer of the law whom the city provides with a State coach and a fanfare of trumpets, going to the courts to award possibly £1000 to one of those persons who had been damaged."

A resolution was passed to the effect that there are two ways by which industrial accidents need not be a charge on voluntary hospitals or on the services of the medical staff: (1) making a charge on industry, which would require legislation; and (2) the development of contributory schemes in connexion with which the services of the staff are recognised in accordance with the policy of the Association.

Pay Beds and the Improvement of British Hospitals.

Dr. CHRISTINE MURRELL, for Kensington, moved:

> That the annual representative meeting, on behalf of the British Medical Association, wishes to emphasise the

conviction that pay bed accommodation is wanted not only for those patients who require operative or specialist treatment, but also for those whose need for such accommodation is due to the fact that they cannot receive suitable nursing and domestic attention in their own homes, so that they may receive the attention they require whilst still remaining under the medical care of their own private practitioner.

Supporting this resolution Mr. H. S. SOUTTAR said that everyone was now asking for hospital treatment and it ought to be made available to the whole community. The next few years would see an enormous development; the poor-law hospitals were to be taken over and brought up to date. Before a recent visit to Sweden he had thought he knew what an up-to-date hospital was, but he had discovered there that his ideas were 30 years behind the times. The hospitals of Sweden were as fine as they could be made; everybody had access to them, and general practitioners could use them for their own patients. We too should have first-class hospitals open everywhere to the public and to medical men, but this would be impossible without help from public sources. He was certain there was no X ray apparatus in this country as good as what he had seen in Sweden. The reason was simple. To keep such apparatus up to date it had to be scrapped every five years and no voluntary hospital could afford that.

Mr. W. MCADAM ECCLES spoke of the need for peripheral hospitals in addition to the great centres of education and specialist treatment. A hospital charging six guineas a week would need 150 beds to pay its way.

The motion by Kensington was approved.

Salaries in the Public Health Services.

Sir ROBERT BOLAM reported that since the beginning of this year the scale of salaries in the public health services has been under consideration by a conference composed of representatives of the profession and of local authorities and that a provisional agreement had been reached for presentation to the Representative Body and the various associations of local authorities.

The more important recommendations agreed to at conferences between representatives of local authorities and the British Medical Association on the salaries of whole-time public health medical officers are as follows:—

1.—Resident Medical Officers. £350, rising by £25 a year to £450, with emoluments to include board, lodging, laundry, and attendance.

2.—Medical Officers employed in Departments (three years' professional experience). £500 rising by £25 a year to £700.

3.—Senior Medical Officers (not being M.O.H.) in charge of services—e.g., school medical officer. £750 rising to £1100.*

4.—Medical Superintendents of Institutions other than Mental Hospitals. £750 (not exceeding 150 beds) to £1100 (over 750 beds), these salaries to include housing accommodation and board.*

5.—Deputy or Chief Assistant Medical Officers of Health. Sixty per cent. of the appropriate minimum commencing salary of the scale for M.O.H.*

6.—Medical Officers of Health. Population not exceeding 50,000, £800. Population exceeding 750,000, £1600 (County Councils and certain rural and urban districts), £1800 (County Boroughs and Metropolitan Boroughs and certain urban districts).*

7.—Salaries for combined posts, £800.

8.—Assistant Medical Officers to Mental Hospitals. £350, rising by £25 a year to £450, with emoluments to include board, lodging, laundry, and attendance. Suitable provision for married assistant medical officers should be made. An additional £50 per annum to those with a diploma in psychological medicine.

9.—General Conditions applying to all appointments. These include provision that travelling and other reasonable expenses incurred in the performance of duties shall be paid; the operation of this scale shall not result in reducing the salary of any medical officer; if the right to terminate a medical appointment on marriage is desired, a specific statement to this effect should be inserted in the advertisement of the appointment; no differentiation of salary shall be made on account of sex.

10.—An Advisory Committee, consisting of eight representatives of various associations of local authorities, eight representatives of the B.M.A., and a chairman appointed by the Ministry of Health, to consider the merits of any case of proposed departure from this agreement, or of difficulty in its application.

11.—Duration of Agreement. From April 1st, 1930, for five years, and thereafter from year to year.

This scale, while it is more inclusive, does not differ substantially from that set out on p. 159 of the Annual Handbook of the British Medical Association. The commencing salary in Section 2 (Medical Officers employed in Departments, who have had three years' experience subsequent to qualification) is agreed at £500 (formerly £600). No scale for the medical superintendents of mental hospitals is set out.

Sir Robert recommended that this agreement, set out above, be accepted as a basis of any further negotiations. It was a compromise, and he would not pretend that he was altogether satisfied with it. In some ways the profession might do better with the present system under which constant watchfulness could enforce the offer of salaries attractive to certain sections of medical men. It seemed desirable, however, especially in view of the forthcoming changes in local government, to meet the local authorities in a conciliatory spirit, and it was hoped that the proposed agreement would give the country for the next five years the type of public health service it ought to have. It would make it possible to say to a young man that the question of entering this service was worth careful consideration.

Mr. E. W. G. MASTERMAN criticised details of the agreement but said that the general feeling must be one of great gratitude to Sir Robert Bolam for doing so much to negotiate it.—Dr. MIDDLETON MARTIN thought it marvellous that any conference should have achieved such a document.—Dr. J. T. D'EWART said it would greatly improve the position of junior members of the public health services, but wished that more could have been done for older men.—Dr. H. W. POOLER and Dr. H. KERR drew attention to certain anomalies in the payment of medical officers; Dr. EUSTACE HILL said that the Society of Medical Officers of Health was not entirely satisfied with the agreement but regarded it as a great advance; and in the course of further discussion, Dr. FOTHERGILL said he had observed a great improvement during recent years in relations between private practitioners and medical officers of health.

The draft agreement was accepted by the meeting.

Motor Accidents.

Dr. J. W. BONE (chairman of the Medico-Political Committee) said it had become a misfortune for a medical man to live near one of the great roads of this country. He had to work by day and by night with very little chance of payment and his lot was all the worse if he happened to be on the staff of the local hospital. All the same the Council felt that it was not the function of a body of doctors to initiate a solution of this problem. He therefore moved:

> That the Representative Body is of opinion that failing the creation of a central fund by some extra tax on motorists or some system of compulsory insurance, including a priority for charges for medical attendance on any claims made, either of which methods would require legislation, probably highly contentious in nature, no satisfactory solution can be devised of the difficulty experienced by doctors in recovering the amount of their charges for treatment rendered to patients meeting with accidents on the road; further the Representative Body is of opinion that no greater case can be made out for dealing specially with the non-payment of fees incurred by persons involved in road accidents, than for those incurred in the treatment of the victims of any other form of accident.

Dr. C. FORBES, for Aberdeen, produced arguments against nearly all these contentions and proposed that the question should be sent back for reconsideration.

---

* In classes 3 and 4 an increment of £50 to the salary every two years to 75 per cent. of commencing salary, provided that no salaries in these classes shall exceed £1100. In classes 5 and 6 it is understood that suitable increases for capability and length of service will be given.

This opinion got spirited support from Dr. J. B. MILLER, who said that Lanarkshire were astounded at the Council's recommendation—in so far as they could understand it. He thought the Council was "shelving the matter in an avalanche of words," and he drew a pathetic picture of the medical man summoned urgently to a motor accident—as often as not to find the smiling face of the countryside unchanged when he got there. Sometimes the patient removed himself; sometimes he was removed by another car; and in any case no doctor would think of attending accidents except from a sense of duty. At the end of the proceedings a constable would often emerge from cover, the reason for his previous modesty being that if he had sent for medical help himself the police would have been liable for a fee. Most motorists were insured against third-party risks. Why, then, should not the insurance company pay the doctor direct, just as (he understood) fire-brigades were paid direct for their salvage?

Dr. R. M. MANWARING-WHITE said he knew that in some areas the police had definite instructions not to send for a doctor so that they should not be liable for a fee; their custom was to ask Tom, Dick, or Harry in the crowd to send for help.

After a brisk discussion, Dr. BONE said he was now convinced that the question was worthy of the Council's further attention, and agreed that it might be desirable to get the views of the big motoring organisations. The resolution was therefore referred for reconsideration—a fate which also overtook the next of the Council's recommendations, namely:

That although it is unsatisfactory that fitness for driving a mechanically propelled vehicle should, as at present it is, be ignored entirely in the granting of a driving licence, the practical difficulties in regard to the position, including that of obtaining a consensus of opinion as to what the disabilities should be, are such that it is inadvisable for the Association at present to make a pronouncement in the matter; further, that no scheme in this respect so far proposed is free from great practical difficulties.

In trying to get the meeting to accept this motion Dr. BONE lucidly set out the practical difficulties with which, he said, the subject bristled, but Dr. FORBES remarked that these had been surmounted in other countries and Dr. DAIN thought the Association should be prepared for future legislation. Mr. BISHOP HARMAN suggested that an ad hoc committee should be set up to consider what, if any, standards of fitness for driving were desirable, and the meeting as a whole clearly favoured this course.

The Noise Nuisance.

An instance of the general desire to set many things right was provided by West Suffolk, who proposed that the Council be instructed to "take steps to secure legislation for the abatement of unnecessary noise." Dr. GRACE GRIFFITH admitted that West Suffolk was the quietest place on earth, but explained that its rural peace only served to emphasise the nerve-shattering noise now made by mechanical pig-feeders and similar devices. Why, she asked, were moving motors obliged to have silencers, whilst stationary oil-engines, from which there was no escape, could be as noisy as they liked? Could not offensive and unnecessary noise at least be scheduled as a nuisance under the Public Health Act? To which Dr. BONE replied that they had tried to do this last year, but Mr. Neville Chamberlain had astutely insisted on knowing just why noise was bad for health, and had eventually referred them to the Minister of Transport as a more appropriate authority. As for fresh legislation, said Dr. Bone, the Representative Body seemed to think its promotion was very easy; but really it was nothing of the kind. This time his plea was successful, and the meeting passed on to the next item on the agenda, which was the Council's new maternity scheme.

A National Maternity Service.

This scheme is intended to reduce maternal mortality and morbidity by ensuring adequate supervision before, during, and after confinement. It is based on the view that not more than 5 per cent. of women require admission to an institution on medical grounds, and it therefore provides for childbirth at home in all save complicated cases, and those needed at hospital for teaching students and midwives.

The midwife will be engaged early in pregnancy, and will thereafter keep the patient under observation. Not later than the thirty-sixth week she will arrange for one or more examinations by the doctor (chosen by the patient), who is to supervise the case, and if any abnormality arises before or during confinement she will call him in at once. The Council holds that the usual routine work of the antenatal centres can be done quite as well at the doctor's consulting room or in the patient's home—an arrangement which secures a continuity of supervision and treatment not at present obtained.

An essential part of the scheme is that medical men should be able to get their patients into institutions and "should, where possible, be allowed to treat those of them so admitted." Such institutions are to be paid for accommodation and nursing of these abnormal cases admitted on the practitioner's certificate, the cost to the service being estimated at £3 per bed for an average of three weeks for 5 per cent. of the total number of women delivered.

Arrangements are further outlined for a postnatal consultation in every case by the doctor, and for the fees of anæsthetists and consultants where these are called in. The proportion of patients who are likely to need the doctor's services during confinement is given as one in ten, payment being at the scale rate of 5s. per case now paid by local authorities. For each case the practitioner will further receive an average of 11s. 6d. for antenatal and 5s. for postnatal examination, whilst the midwife will probably get about £2 10s. for her services. The "handy woman" has no place in the proposals, but a "home help" will still be required and will usually be paid for out of maternity benefit under the Insurance Acts.

The scheme is intended to apply to all women now entitled to this benefit—i.e., insured women and the wives of insured men—together with other women of similar economic status. The estimated cost on an assumption of 500,000 deliveries per annum is about £2,022,000, which would be offset by the saving of the fees at present paid by the patients or on their behalf. It is suggested that the service should be provided on an insurance basis via the National Health Insurance machinery, and it is stated that an additional contribution on behalf of employer and worker together of 0·4*d.* per week for each insured person, with 0·2*d.* per week from the State, would provide all the money needed. For participants outside National Health Insurance the necessary premiums would be otherwise arranged.

A Brisk Discussion.

Dr. DAIN described the proposals as an attempt to reproduce throughout the country the essential features of maternity services which had shown excellent results in practice. Modern teaching favoured confinement in an institution, but the figures supplied by some of these services showed that labour could be conducted equally safely in the houses of the poor. The scheme permitted free choice of doctor and midwife; it provided that one medical man should see the patient through from start to finish; and it was cheap in the sense of being efficient and economical. It would improve the status of the midwife and encourage a better class of woman to take up this work, and it emphasised the importance of antenatal examination, to which some practitioners were not yet fully alive.

Dr. B. H. PAIN, for Tunbridge Wells, objected strongly to a note in the scheme which says that any woman who wants a doctor to attend her in normal labour must engage him at her own expense. No national scheme, he said, should prevent a woman having her own doctor in attendance. Moreover, the delegation of all normal childbirth to midwives meant that medical men could never acquire the experience necessary for the proper conduct of difficult cases. The proposals were simply proposals for endowing midwives and they would not attract a single medical man to the practice of midwifery. He could have understood their being presented by the Central Midwives' Board or the Society of Medical Officers of Health; but to find them put forward by the B.M.A. was not only disappointing but disillusioning.

Dr. D. Roxburgh traced the decline of midwifery to the passing of the Midwives Act. The wise practitioner no longer undertook confinements, for instead of having 100 cases a year—the rough with the smooth—he got ten difficult cases without any compensating change in the rate of payment.

Dr. James Young pointed out that at all events the maternal mortality-rate was not increasing, and spoke of the work of the Queen Victoria Jubilee Nursing Institute, which recorded a rate of only 1·3 to 1·5 per 1000—one-third of the average. He held that the proposed scheme provided in an unprecedented way for coöperation between doctor and midwife.

Dr. C. M. Stevenson said it was true that the scheme did not benefit the profession financially, but that could not be helped. Midwives were taking over more and more of this branch of practice, and on the whole they could do more for their patients than a doctor could. It would be well to accept a scheme like this which at least gave medical men a share in the work.

In further discussion it was pointed out that a woman in childbirth has a right to ask for alleviation by anæsthetics and drugs which at present can be given only by medical men. More than one speaker said the profession must make up its mind whether it does or does not want to do midwifery. Advertisements of practices suggested that it did not; and it was no good to pass resolutions at the Representative Meeting if they were not going to be backed up at home when the night bell rang. Dr. Brackenbury said the object of the scheme was to make childbirth as safe as it could be made, but if it was proposed that a doctor as well as a midwife was to attend every confinement—or even every confinement in which the patient asked for a doctor—then the scheme would never be accepted by those responsible for the national finances. This argument was reinforced by Dr. Dain's remark that at the moment there is no public demand that a medical man should be available in every case. So long as the present maternity benefit was available he was satisfied that no injustice would be done to any woman who particularly wanted a doctor to attend her. He said that one of the merits of the scheme was that it had nothing to do with endowment of the profession, and that all along they had been looking at it from the point of view of the women who were to benefit.

With minor emendations the scheme was approved by the meeting.

The Maternal Mortality Inquiry.

A brief exchange of opinion on the reaction of practitioners to the questions of a departmental committee drew from one representative the epigram: "What is worth doing is worth being paid for, and what is not worth being paid for is not worth doing." But this was far from reflecting the spirit of the hour, and the following recommendation of Council was approved:—

> That as the giving of information to the medical investigator who will fill up the form of inquiry issued by the Departmental Committee on Maternal Mortality is regarded by the Association as a voluntary contribution on the part of the medical profession to a scientific inquiry on a question of pressing public importance, the Association is of opinion that no fee should be charged for the service and none accepted if offered.

Psycho-analysis and its Critics.

Four years ago Dr. L. A. Parry raised this subject because experience of certain unfortunate cases had persuaded him that psycho-analytical methods were capable of doing a great deal of harm, especially to young people. He asked the Association to issue a public warning against these dangers, and in 1926 a committee was appointed under the chairmanship of Dr. R. Langdon-Down to investigate psycho-analysis in all its bearings. (When the report of this committee was issued last month we gave some account[1] of the findings and explained that the terms of reference were held to cover only the views and methods of Freud and his school.)

Dr. R. Langdon-Down proposed that the report of the Committee on Psycho-analysis appointed in 1926, should be accepted as discharging their instructions. The Representative Body was prepared to agree with Dr. F. H. Bodman's opinion that in the course of wide reading he had never come across a fairer exposition of the subject. At the same time it listened sympathetically to Dr. Parry's objection that not enough stress was laid on the dangers he had in mind. He moved a resolution regretting "that more emphasis has not been laid [in the Report] on the very real and serious dangers, specially to children and adolescents, of any system of mental therapy which postulates a sexual basis as the sole or preponderating cause of nearly all neuroses and pathological mental conditions." As a member of the Committee during its four years' deliberations Dr. Parry declared himself more than ever convinced of the harm that might be done by psycho-analysis, which postulated, he said, that sex was at the bottom of almost all mental and nervous departures from the normal. The Freudians thought that head-nodding, thumb-sucking, and similar disorders were associated with the Œdipus complex, and to treat children on this basis must obviously put sexual thoughts and desires into their heads and thus promote objectionable conduct later on. Mr. E. B. Turner warmly assented and told of the trouble he had had in "cleaning up the mess" in the minds of young people who had been psycho-analysed. He thought that perfectly healthy adolescents sometimes suffered both physical and mental damage by being encouraged to "think of things they had never thought of, and dream of things they had never dreamt of," and if he was told that those he had in mind had gone to the wrong kind of psycho-analyst—well, all he could say was that there were a lot of the wrong kind about. Similar views were evidently held by a considerable number of those present, many showing themselves suspicious of psycho-analysis, but after Dr. Parry's opening speech no time was lost before Dr. M. G. Biggs, one of the senior members of the meeting, pointed out that in scientific discussion there should be no question of prejudice. A more detailed defence of the report was offered by Dr. R. G. Gordon, hon. secretary of the investigating committee, who admitted that harm had been done in the name of the method, but urged that this did not condemn it any more than antiseptic surgery was condemned by the errors of its earlier practitioners. Dr. Parry was not fair, he said, in stating that Freud and his followers "postulated" a sexual basis for nervous disorder. They did not; they said they *found* it—which was a very different thing. It was not the business of the committee to adjudicate on the dangers of psycho-analysis unless definite evidence was laid before them; none of the cases brought to their notice had supported the statements made by its opponents, and he doubted whether Mr. Turner's cases would hold water if properly criticised. This brought the sharp rejoinder from Dr. Parry that it was almost impossible to prove damage in such a case, especially to a committee; "but suppose I hand a boy a tin of gunpowder and a match, must I produce his charred body before I am believed?" Dr. Parry was again equal to the occasion when Dr. C. M. Stevenson asked the meeting to stop its heresy-hunting and think of the verdict of posterity. If the theory was true it must be accepted, said Dr. Parry; but was all criticism a heresy hunt? When the French Government 100 years ago set up a committee to investigate morphia, would they have shown intolerance in drawing attention to the dangers of this drug? As for the verdict of posterity, Dr. J. T. D'Ewart pungently remarked that he was thinking not of posterity, but of his own patients and of how they were to be protected from psycho-analysts who were not properly trained. Whether or no the best practitioners of psycho-analysis were safe, there were people going about under the same flag who were undoubtedly a public danger here and now, quite apart from questions of posterity. A cognate view was taken by Dr. C. E. DOUGLAS, who objected to the widespread assumption that Freud had discovered the psychological influence of sex and had invented the subconscious mind. The difference between schools of thought on the subconscious was, he said, that James separated it from the conscious by a threshold which was clean, whereas the threshold recognised by Freud was covered with muddy footmarks. Dr. DOUGLAS vigorously disapproved of certain aspects of the report, and this and other critical opposition to it might have carried the day but for opinions expressed by three of those who had served on the committee. Dr. PETER MACDONALD said that he was clear, at any rate, on two points: First that psycho-analysts (in the true and proper sense) were not charlatans, and secondly that "proof of the dangers of psycho-analysis appears to disappear when probed." After sitting on the committee for three years he did not *know* whether the method was dangerous to children and adolescents, but he was sure that the representatives ought to be in the same position and he begged them not to commit themselves to what Dr. D. CLOW called a pontifical announcement when they did not know, and they knew that they did not know. Dr. LANGDON-DOWN admitted that there must be dangers in any form of exploratory mental therapy, but thought that none had done more than the psycho-analysts themselves to point out these risks and guard against them. Lastly Dr. E. K. LE FLEMING, in giving further approbation to the report, wondered why no case of damage done could be produced if they were indeed so common.

---

[1] The Lancet, July 6th, 1929, p. 31.

It will be seen that woven among strong feelings about a practical problem there was in this discussion a very general desire to keep an open mind. After serving on the investigating committee Dr. LE FLEMING summarised his feelings in the quotation, "Oh what a dusty answer gets the soul, hotfoot for certainty in this our life"; but this was a negative attitude compared with that of Dr. J. S. MANSON and several other representatives who obviously (like Matilda's aunt) kept a strict regard for truth. With so many adorning the tale it fell, perhaps, to Dr. L. W. BATTEN to point the moral of greatest practical importance. The meeting was very nearly being asked, he said, to declare that nothing so unpleasant as psycho-analysis could possibly be true, and this was an attitude of mind concealing dreadful dangers. People who thought experiments on animals particularly unpleasant were apt to say that such experiments were therefore wrong, and that deductions from them must be unsound. Hence came the necessity to argue that staphylococci did not cause boils, or tubercle bacilli tuberculosis. "We must not do things like that," said Dr. BATTEN; and perhaps because they saw this hideous abyss in front of them the representatives by a large majority threw out Dr. PARRY's resolution calling attention to the dangers of psycho-analysis. The Psycho-analysis Committee were thanked for their services without comment on the nature of the report.

Election of Chairman and Vice-Chairman.

Dr. HAWTHORNE was re-elected chairman of the Representative Body for the coming year, and Dr. ARNOLD LYNDON vice-chairman.

(To be concluded.)

RATING OF SUNDERLAND HOSPITALS.—Under the new scheme for the unification of rating, the assessment of Sunderland Royal Infirmary was increased to £700, while that of the Aged Seamen's and Widows' Homes at Bishopwearmouth was raised to a point which threatened their closure. The local assessment committee has now decided to rate the Infirmary and the Children's Hospital at the nominal figures of £16 and £5 respectively, with similar large reductions for the other institutions.

THE SCOPE OF CANCER INQUIRY.

To the Editor of THE LANCET.

SIR,—The report of the British Empire Cancer Campaign (summarised in your issue of July 13th) is, as usual, an admirable record of excellent work, but, if I may be allowed a criticism, it seems to me that progress in the investigation of the causation of cancer might be more rapid if the tacit assumption that cancer and sarcoma are different from all other kinds of tumour were dropped, and the scope of the inquiry were enlarged to embrace the mode of origin of all tumours.

Tumours start either from a single cell or from a group of cells which have the same origin, serve the same function, and live under the same conditions. For some reason as yet unknown, these cells at different stages of their development suddenly cease to do any work or to develop any farther, and instead devote the whole of their energy to indiscriminate multiplication. The cause is the sudden assertion of the power of asexual reproduction which is inherent in every cell, more or less in virtue of its descent, but which is kept under control, unable to exert itself so long as the cell continues to expend its energy in doing its own special work. The result is the formation of a growth with a life of its own, distinct from that of the parent that gave it birth, though absolutely dependent on it, drawing all the nourishment it requires from the parent, and doing nothing for it in return, capable of growing and thriving while the parent starves, and only dying when the supply of nourishment is cut off by some local cause, or by the death of the parent—in other words, what may be regarded as a parasite.

The germ cell, whether of the race or of the individual (which, in the course of its development, recapitulates the evolution of the race), possesses the power of growth and reproduction in its fullest measure. It can divide into two and each half can form a separate and perfect individual. Or the separation may be incomplete, or the division may be unequal, when some monstrosity will result. Every part of it possesses this power, and the earliest cells into which it divides inherit it, and can behave almost as independent organisms, capable of moving from one part to another. But as the cells continue to multiply, and the organism to increase in size, this stage of semi-independence comes to an end. Certain groups of cells become marked off by their position or relation to the rest as specially adapted to carry on certain kinds of work, and organs with definite functions begin to make their appearance. One of the earliest of these groups to be marked off in this way is that to which is assigned the function of reproduction and the preservation of the race.

At once the organism becomes divided into two parts, very unequal in size. One, the smaller of the two, is concerned solely with the function of reproduction and the preservation of the race. It does nothing else. It has no other kind of work, and as it is restricted to this one function, it becomes more and more efficient, until bisexual reproduction is evolved, and ultimately the sexes become separate. The tumours that grow from these cells are imperfect representations of organs or tissues, arranged, so far as circumstances permit, in a more or less orderly manner. Many of them are capable of a certain degree of development, and some can carry on a useless kind of work. The reproductive energy of the cells has been released in some way from the control that held it in check, and they are free and unfettered to develop as far as the influence of surrounding structures allows them.

The other, by far the larger of the two, has nothing to do with the preservation of the race, and is given up altogether to the maintenance of the individual. The cells of which it is composed undertake everything that is necessary for this purpose. The work is of the most varied character, and their structural development, which is determined by the character of their work, is naturally equally varied. Little by little, as they become more and more highly specialised, the reproductive power which they originally possessed in common with their fellows grows less and less. Traces of it may be seen in larval forms, especially of aquatic animals in which the reproduction of limbs is still possible, and in a much more rudimentary form, even in mammalian embryos, but so far as the higher animals are concerned reproduction is limited to the formation of simple tissues, and even in these to those that are not too highly specialised. Structures such as the elements of the organs of the special senses or of the nervous system have lost all power of reproduction, and tumours formed from them are almost unknown.

As the reproductive power is limited in this way, the only tumours that can be formed by these tissues are composed of simple elements, without order, arrangement, or shape, other than is imposed upon them by surrounding structures. Their clinical character depends upon the stage of growth reached by the parent cell before its development came to an end. If it had reached, or almost reached, its final adult form, as for example in the case of fibrous tissue, the tumour is formed of similar adult tissue, and increases slowly in size, pushing surrounding structures to one side. But if on the other hand it was still in the embryonic stage, with all its primitive powers of multiplication and migration unimpaired (and myriads of such cells are constantly being produced throughout life), the tumour is composed of similar rapidly growing cells, capable of invading surrounding tissues and of being carried, partly actively, partly passively, to other regions of the body, where they can grow into tumours like the original one. As development is a continuous process without break or interruption from the very earliest age up to the perfection of specialisation, and this sudden arrest can apparently take place at any stage, the tumours that grow from these cells necessarily shade imperceptibly into each other, and no line of separation can be drawn between them, no matter how much they may differ from each other clinically. Characteristic types can be, and must be, described, around which the majority of these growths can be ranged, but in between these there are numberless gradations of which no one can say whether they belong to one or the other, or whether they may not belong at one time to the one and at another to the other. The distinction is a clinical one.

The simultaneous occurrence of these three phenomena which appear to be essential to the growth of tumours—viz., the cessation of all functional activity, the arrest of development at whatever stage the parent cell may have reached, and the output of all the reproductive energy it still retains, must be associated with, if not caused by, a profound change in the metabolism of the cell. But the agent that can bring about this change is still unknown. Mechanical irritation undoubtedly plays a part, for tumours develop most frequently in places exposed to irritation, but it is open to question whether it is sufficient by itself. Information is more definite about chemical substances such as soot, some forms of tar, and mineral oils, especially when their action is long-continued and associated with irritation. There is no doubt as to what they can do. Very possibly the occurrence of tumours of the bladder in those engaged in aniline dye works, and the development of epitheliomas in cases of unrelieved congenital phimosis are instances of purely chemical action. X rays, which can kill cancer cells and are at the same time the most certain agent for producing cancer known, must act by influencing the metabolism of the cells exposed to them. The first change is an interference with the function of the skin. It becomes dry and harsh. Then the development of the epidermic cells becomes imperfect. Little irregularities appear upon the surface. Definite warts and papillomata follow, and if exposure is continued epithelioma is certain. That these and certain chemical substances are capable of effecting changes in cell metabolism cannot be denied, but as yet too little is known to allow even speculation upon the nature of these changes. Hope seems to point in the direction of tissue culture, and it is not impossible that the problem of the causation of cancer will ultimately be solved by the study of the conditions that influence the function of reproduction.

I am, Sir, yours faithfully,

C. MANSELL MOULLIN, C.B.E., M.D., F.R.C.S.

THE DEVELOPMENT OF PULMONARY TUBERCULOSIS.

To the Editor of THE LANCET.

SIR,—Dr. Morlock's valuable paper in your issue of July 13th and Dr. Toussaint's letter in the following issue draw attention to the simulation of influenza by incipient phthisis. Radiology has, indeed, placed beyond dispute the statement that the onset of pulmonary tuberculosis, especially in young persons, is usually an acute process. It is therefore not surprising that the earliest manifestations of the disease are often lightly dismissed by the patient and occasionally by the doctor as the effects of an "influenzal cold" or "chill." Mistakes of this kind are indeed inevitable unless the possibility of tuberculosis is kept constantly in mind. The results may be disastrous alike to the doctor's reputation and to the patient's chances of recovery.

Inquiries as to the first symptons of disease in a series of 50 adolescent and young adult female consumptives who came under my observation in the period 1927–28 gave the following results: Cough (accompanied by lassitude in nearly half the cases) 64 per cent.; haemoptysis, 18 per cent.; influenza, chill, 12 per cent. During the winter rush it is impossible for many practitioners to examine carefully every patient complaining of cough. I think, however, that mistakes in diagnosis might be reduced to a minimum in the busiest urban practice if the following points were remembered:—

1. Cough in a young person, especially in one of the female sex, should always be regarded as a possible danger signal. If persisting for more than a week the spit should be tested for tubercle bacilli. If the result is negative and symptoms continue the test should be repeated on at least two further occasions.

2. A hæmoptysis of one teaspoonful or more should be regarded as evidence of tuberculosis unless other cause can be demonstrated. The only other common cause of pulmonary hæmorrhage in young persons is bronchiectasis. A hæmoptysis which the patient seeks to minimise is almost always of sinister import, one that a patient delights to describe is seldom of any great significance.

3. In physical examination auscultation is more important than percussion—despite the text-books. Moist râles in the upper half of the lung should be regarded as presumptive evidence of tubercle. Dry crackles or superficial rustles should be disregarded. A crepitation is a sound heard not a sound imagined. The common site of early infiltration, as Dr. Morlock has emphasised, is below the clavicle, where in a typical case the skiagram shows a roughly triangular shadow with its base outwards towards the axilla. The infraclavicular and axillary regions should therefore be auscultated with special care, as also the region internal to the vertebral border of the scapula which includes the *zone d'alarme*. If the patient is instructed to give a short cough and take a breath every time the stethoscope is applied the whole chest can be auscultated in a couple of minutes.

The average practitioner cannot command radiograms of the fine quality necessary for chest work, and though a skiagram is always valuable and sometimes essential for correct diagnosis, a poor film is worse than useless. Temperature, pulse, and weight records are obviously desirable but not always obtainable. If, however, due regard were always paid to the criteria indicated above, very few cases of incipient tuberculosis should be missed. A history of possible exposure to infection is not likely to be ignored by a family doctor.—I am, Sir, yours faithfully,

W. BURTON WOOD.

Park-square West, N.W., July 21st, 1929.

THE MEDICAL DIRECTORY.

To the Editor of THE LANCET.

SIR,—The annual circular has been posted to each member of the medical profession. If the form has not been received, a duplicate will be sent on request. We shall be grateful for the return of the forms by an early post.—We are, Sir, yours faithfully,

J. AND A. CHURCHILL.

40, Gloucester-place, W.1, July 18th, 1929.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

LOCAL GOVERNMENT (SCOTLAND) ACT AMENDMENT BILL.

REPLYING to Mr. BALDWIN (Leader of the Opposition) in the House of Commons on Wednesday, July 17th,

Mr. MACDONALD, Prime Minister, said that the Local Government (Scotland) Act Amendment Bill was circulated for the information of the House so that they might see what was best to be done in the circumstances, and he had made it clear that unless there was some chance of getting the Bill through Parliament within a reasonable time it would be quite impossible to proceed with the measure. He wished to have an opportunity to pursue his investigations further in order to see whether it would be possible to proceed with the Bill, and he promised to make a final statement as to its fate on the following day.

On Thursday, July 18th, in reply to Sir ARCHIBALD SINCLAIR,

Mr. MACDONALD said that he had made further inquiries about the chances of the Bill in relation to the business which must be finished this month. He had also had representations of both sides of Scottish opinion. With very much regret he saw no prospect of this Bill passing all its stages in this House and in the House of Lords in time to be effective, and, therefore, he did not propose to ask the House to discuss the measure further.

Miss LEE asked if there was any insurmountable reason why the House should not sit a little longer to consider this Bill. Profound disappointment, and indeed indignation, would be caused in Scotland if it was dropped at this stage, especially as many members on the Labour benches felt that they had a full assurance in that House that this matter would, above all others, be given consideration before the summer recess.

Mr. DUNCAN MILLAR: Is it not the case that on Wednesday last the Prime Minister gave this House an undertaking that he was going to save the education portion of the Bill, and is the right hon. gentleman aware that his action will cause great disappointment to the authorities and the people in Scotland who were relying on what the right hon. gentleman had said?

Mr. MACDONALD said that the description of what he had said in the previous week was most inaccurate. He said exactly the opposite. What the Government had to face was whether the Bill could be got through in time.

Mr. MACPHERSON: Are we to understand from my right hon. friend that there will be no further inquiry into Scottish local self-government, or into Scottish local government?

Mr. MACDONALD: That part of my statement (which was a definite statement) remains.

Sir A. SINCLAIR: If the inquiry is going to take place in October, surely it will be a *post mortem*?

Mr. MACDONALD: In any event, four-fifths will be.

Mr. HARDIE: Is the Prime Minister aware that this was a major subject at the General Election?

Mr. MACDONALD said that at the General Election he had stated that there was a possibility of education being separated from the rest of the Act, but that he was not sure and would look into it, and if anything could be done a Labour Government would do it. He had made it clear that, as far as the Act itself was concerned, it could not be annulled or changed, but as regarded the whole of the altered Scottish local government machinery the Labour Party, if it had the enjoyment of power during a full Parliament, would certainly before going to the country complete the inquiries on the subject and take action.

Mr. MACPHERSON asked leave to move the adjournment of the House for the purpose of discussing a definite matter of urgent public importance—namely, "the failure of the Government to suspend the operation of the Local Government (Scotland) Act, 1929, or to proceed with its Bill to amend the said Act."

Fewer than the requisite 40 members intimated their support of Mr. Macpherson's request, and the House therefore proceeded to the Business of the Day.

COLONIAL DEVELOPMENT BILL.

On Wednesday, July 17th, Mr. LUNN, Under Secretary for the Colonies, in moving the second reading of the Colonial Development Bill (a measure to enable the State to grant financial assistance to schemes of development overseas with a view to helping employment in this country), said that when the financial resolution on which the Bill was based was being discussed several speakers had raised the question of medical services, and had urged that they should be considered in any scheme of colonial development. There had been many schemes undertaken not only in this country but by other countries in recent years on which that matter had been considered very seriously, and taken in hand, and they had proved the wisdom of giving attention to the health conditions of those who laboured in these great enterprises. It was equally important that health conditions should be considered even in smaller enterprises. He could assure the House that in any schemes of colonial development the medical services and medical research for the improvement of health conditions would find a very important place.

Lord EUSTACE PERCY said that the Lord Privy Seal and the Under Secretary for the Colonies had both laid stress on the grants for health purposes. Those grants, if they were to be permissible under the Bill, would be so under the words "any other means" in Section 1. If they mentioned "any other means" and specified one of those other means, "including surveys," they ran great risks of finding that health would be excluded. That was a Committee point, but he would ask the Government to give their attention to it.

Sir OSWALD MOSLEY, Chancellor of the Duchy of Lancaster, said that quite clearly under the wording of the Bill animal health was included, because anything relating to agriculture concerned animal health, and therefore animals were within the purview of the measure. He thought that Lord Eustace Percy, however, had referred to human diseases. He (Sir O. Mosley) was advised that within the framework of the Bill it was possible to include diseases affecting those engaged in industry and which impaired their efficiency. Certainly such diseases as hookworm, which notably impaired the efficiency of those engaged in industry, could be dealt with under the Bill. In fact, whenever they came to the consideration of industrial efficiency they must at once be led to the physical condition of those engaged in the industry, and it would be a very narrow and very mistaken reading of the purposes of the Bill if the great human element upon which, after all, all industrial efficiency rested in the first degree, was excluded from its purview.

Dr. VERNON DAVIES: Why not include it specifically?

Sir O. MOSLEY said that he had been trying to explain that it was included.

Dr. VERNON DAVIES: With great respect to the hon. baronet, I do not agree with him.

Sir O. MOSLEY said that after the explanation he had given he could only assure Dr. Davies that his fears were not justified.

The Bill was read a second time.

On Thursday, July 18th, the House went into Committee on the Colonial Development Bill, Mr. R. YOUNG in the chair.

Power to Make Advances for the Purposes of Colonial Development.

On Clause 1, Dr. MORGAN moved an amendment to make it clear that schemes for benefiting health or labour conditions were included under the clause. He said that on the second reading debate Sir O. Mosley had stated that he thought that health matters were included in the Bill. The word "health" was not mentioned in the whole of the Bill. Health was a very important subject in the Crown Colonies, and especially in the West Indian Islands. The only possible reference in the Bill which could be included under health was the question of the drainage of land and swamps for the removal of malarial conditions. The disposal of sewage in many of these islands was very primitive at present, and he wanted to make it possible for sewage schemes to be brought within the scope of the measure, as such schemes affected tourist traffic, trade, and the general health of the community. He also wanted to make sure that if a company started a new industry, or to develop an old one, such company should provide proper housing and working conditions for the people engaged in the industry.

Sir O. MOSLEY said that since the second reading debate he had looked closely into the question of whether this matter was covered by the Bill. The impression which he had already stated to the House was confirmed, and he was satisfied that health was included. He was quite prepared, however, if hon. Members desired it, to consider the inclusion of specific words at a later stage to cover this point.

Dr. MORGAN withdrew his amendment.

Later Sir O. MOSLEY moved to include the words "the promotion of public health" in the clause. He said that indigenous inhabitants would be covered by the words of his amendment, as well as all forms of settlers, and he hoped that hon. Members on both sides of the House would be satisfied that it definitely established the principle of public health.

The amendment was agreed to.

The Committee stage of the Bill was concluded.

THE HOUSING SUBSIDY.

The Housing (Revision of Contributions) Bill was read a second time.

On Monday, July 22nd, Mr. A. GREENWOOD, Minister of Health, in moving the third reading of the Housing (Revision of Contributions) Bill said that it was a modest measure which proposed merely to continue for the present the existing housing subsidy under the 1924 Act and to discontinue, as the late Government suggested, the subsidy under the Act of 1923. He said that he had been criticised by Sir Kingsley Wood for not having done more. He had not done more because he was primarily concerned to avoid discontinuity of building and to give the Government time to produce a Bill of a much larger kind. The prolongation of the subsidy under the 1924 Act did not prejudice in any way what might happen in the future. If he could get local authorities, as he understood he could, to continue their building pending a larger measure, then he would consider this Bill had been amply justified.

Mr. T. SNOWDEN said he took exception to the speech of Lieut.-Colonel Fremantle in which he said that medical officers of health urged as strongly as they could that the Treasury should reduce the vast sums which were spent by the late Government on housing in order to provide more money for other important health services which were calling out for treatment. He (Mr. Snowden) regretted to hear that speech, because if the subsidy would encourage housing—and he believed it would—it would remove evils caused by bad houses and in consequence reduce possible expenditure on the other matters to which Colonel Fremantle had referred.

Lieut.-Colonel FREMANTLE: I only said that it was an extremely extravagant way of doing it.

Mr. SNOWDEN said that it was rank waste to have to spend so much money on evils which were caused directly by bad housing. It was better to spend money on housing than have to spend it on building hospitals.

Lieut.-Colonel FREMANTLE: The whole point is waste. So far as it goes to improving housing we are all in favour of it.

Mr. SNOWDEN said he differed from Colonel Fremantle and he would like to think that the hon. Member did not represent the views of other medical officers of health, or even of the medical profession.

Miss RATHBONE urged that after the lapse of ten years a Select Committee was needed to consider the housing problem from the tenancy side, to see how far they could erect enough houses and to see that those houses passed into the hands of those whose housing needs were the sorest. At present the housing policy of this country might be compared to our having built at vast cost a reservoir intended to relieve the thirst of people who were dying of thirst and then allowing the first call on the water to go to those who wanted water only for the watering of their roses. The problem of incapacity to pay an economic rent was a personal problem and could never be solved, whatever the subsidy might be, by so mechanical a device as a flat-rate arithmetical equal reduction of rent by the amount of the subsidy upon the houses built by the local authorities.

Dr. VERNON DAVIES said that Mr. Chamberlain, the late Minister of Health, as a result of his prolonged experience, came to the conclusion that a subsidy had a distinct effect on the cost of houses; that if the subsidy was raised there was a tendency for the cost to rise, and, on the other hand, if the subsidy was reduced there was a tendency for the cost of houses to be reduced. The present Minister of Health took exactly the opposite view. Although the Minister would not deny that subsidies might have some effect upon prices he was not concerned so much with the matter of prices as with the building of houses as quickly as possible. That helped the building of houses, but it did not help to let them at an economic rent which people could afford to pay. He (Dr. Davies) would suggest that the Minister of Health had a sufficient amount of information to enable the House to come to a considered opinion on the subject, and when the scheme which was germinating in Mr. Greenwood's brain came before the House next session it might be well if a White Paper was laid before Parliament giving the whole arguments for and against a subsidy, what it had done in the past, and what it was expected to do in the future. If the Minister of Health was right in his theory it would be to his great advantage and to the advantage of the country. If, on the other hand, the argument pointed in the other direction he was sure that Mr. Greenwood was a big enough man to acknowledge it. His (Dr. Davies's) belief up to the present time was that Mr. Chamberlain was right in his theory, and that the Government were making a grave mistake.

The Bill was read the third time and passed.

HOUSE OF LORDS.

TUESDAY, JULY 23RD.

The Problem of Slum Clearance.

Lord ARNOLD, Paymaster-General, moved the second reading of the Housing (Revision of Contributions) Bill. He said that it was a temporary measure. The whole question of housing and slum clearance was receiving the constant and earnest attention of the Government. In due course their plans would be made known.

The Earl of ONSLOW said that the Bill was a mischievous and retrograde measure.

The Bishop of SOUTHWARK said that the problem of slum clearance had never really been tackled. It never would be tackled until a large number of new houses, at low rents, were built within reach of their occupants' work. If the problem was to be solved they would be driven back on the policy of giving special children's allowances for rent. Any scheme for dealing with the slums would cost large sums of money, but when the conditions under which the people lived were realised it would be felt that almost any expenditure was worth while. A recent survey of housing conditions in Southwark, by competent and experienced investigators, showed that the condition of affairs was horrible. In street after street they found people living under conditions of darkness, dampness, and overcrowding. Sometimes a man, his wife and his children would be found living in a basement which had long since been condemned as unfit for human habitation. The investigators quoted the fact that the Medical Officer of Health for Southwark had stated that in one year there were 10,000 houses in Southwark which were not in a reasonably fit state in all respects for human habitation. The matter, the Bishop of Southwark continued, was far too large for any borough or Medical Officer of Health or any individual to deal with; it must be tackled by the nation as a whole. He was glad that the Government had decided not to reduce the present subsidy. The present Bill would give the Government time to prepare their plans for a measure dealing with the slums which, he hoped, would be comprehensive and courageous.

The Bill was read a second time.

HOUSE OF COMMONS.

WEDNESDAY, JULY 17TH.

Medical Service in Tristan da Cunha.

Mr. SCURR asked the Under Secretary for the Colonies how often the island of Tristan da Cunha was visited officially; what arrangements were made to meet any emergency medical or other call from the inhabitants; and if there was a wireless station on the island.—Mr. LUNN replied: There is no regular programme of visits to Tristan da Cunha. His Majesty's Government, however, have endeavoured to arrange that at least one steamer carrying supplies, &c., calls at the island each year. On learning in April last of a threatened food shortage, His Majesty's Government provided the funds necessary to ensure the call at Tristan of a vessel carrying relief stores. I understand that a wireless apparatus, capable of receiving messages from England, Buenos Ayres, and New York, was installed on the island last February.

Prohibition of Night Baking.

Mr. MANDER asked the Home Secretary whether it was the intention of the Government to include in the forthcoming Factories Act a clause prohibiting night baking.—Mr. CLYNES replied: This question will be considered by the Government in connexion with the Factories Bill, but I am not at present in a position to make any statement.

Private Mental Hospitals.

Mr. SORENSEN asked the Minister of Health how many private lunatic asylums and mental hospitals existed in England and Wales; the number of patients therein, and the number of discharges therefrom during last year.—Miss SUSAN LAWRENCE (Parliamentary Secretary to the Ministry of Health) replied: On Jan. 1st, 1929, there were 69 private institutions under the Lunacy Act, and 4640 patients therein. There were 742 discharges during 1928.

Use of White Lead Paint.

Mr. MANDER asked the Home Secretary if the Government were prepared to ratify the International Labour Office Convention, 1921, concerning the use of white lead in painting.—Mr. CLYNES replied: Ratification would have to be preceded by legislation for the amendment of the present law, and all I can say on the subject at the present moment is that it will be considered with other questions in connexion with the proposed Factories Bill.

THURSDAY, JULY 18TH.

Pensions Medical Officers.

Dr. MORGAN asked the Minister of Pensions the total number of medical practitioners now employed by the Ministry on a sessional basis, and how many of those were specialists.—Mr. ROBERTS replied: The number of medical officers employed by the Ministry on a sessional basis was, during the latest period for which information is available, on an average 363, of whom approximately two-thirds were specialists.

Treatment Allowances in Tuberculosis Cases.

Mr. SIMMONS asked the Minister of Pensions whether he would reverse the present practice regarding tuberculosis cases, whereby ex-Service men who were knocked off work by the pensions doctor were not granted treatment allowances until they entered an institution, by ordering that the payment of such allowances should date from the day of relinquishing work under the advice of a pensions doctor.—Mr. ROBERTS replied: My hon. friend is, I think, under a misapprehension. In any case where the Ministry's medical adviser considers it desirable, in the interests of treatment which has been recommended, that a man should abstain from work pending admission to an institution, it has always been the practice to pay treatment allowances in the interval, subject to the usual conditions.

Pensions Final Awards.

Dr. MORGAN asked the Minister of Pensions the total number of final awards made in the half-year ending June 30th last; the total number of pensioners now receiving final award pensions; the number of such cases who had appealed for re-assessment in the last two years; and whether he would consider application for review if such cases were now submitted to him.—Mr. ROBERTS replied: The total number of final awards made in the six months ending June 30th last was 24,077. The number of pensioners now receiving final awards of life pension is about 390,000. During the past two years 7529 appeals have been made to the Assessment Appeal Tribunals. The arrangements which I was enabled to make five years ago for the correction of serious errors of final award are still in operation.

Unqualified Nurses in Mental Hospitals.

Mr. AYLES asked the Minister of Pensions the number of unqualified nurses at present employed in the mental hospitals under his control; and whether he would take an early opportunity to see that only certificated male nurses were employed in State institutions.—Mr. ROBERTS replied: The male nursing staff employed in institutions dealing with cases of mental and severe nervous disorder is required, to the utmost extent possible, to be qualified by experience in the handling of such cases, and 25 out of the 62 male nurses employed in nursing *certified* cases have the additional qualification of a certificate. With regard to the second part of the question, I understand that the Board of Control have not found it practicable or desirable to advise in public mental hospitals the standard suggested by my hon. friend.

Asylum Workers' Superannuation.

Mr. RAMSBOTHAM asked the Minister of Health whether, in view of the need for the coördination of superannuation of officials both in asylums and mental deficiency institutions as well as in the mental wards of poor-law institutions, and as these would in the main in future come under the same control, he would consider the desirability of ensuring that no superannuation provisions should militate against free interchange of qualified mental nurses between one type of institution and another.—Mr. GREENWOOD replied: I will consider the question raised by the hon. Member in connexion with any proposed legislation amending the relevant Superannuation Acts.

Mental Defectives.

Mr. SORENSEN asked the Minister of Health to state the ascertained number of mental defectives under and above 16 years of age, respectively, in England and Wales, and the number of each category in suitable institutions; and whether he proposed to take steps to ensure the provision of adequate accommodation for these persons.—Mr. GREENWOOD replied: The total number of mental defectives ascertained by local authorities was 66,468 on Jan. 1st last. Of these 19,188 were maintained in institutions. I regret that the available statistics do not enable me to differentiate between those under and those over 16 years of age, but the total given does not include feeble-minded children for whom the local education authorities are responsible. The problem of ensuring the provision of adequate accommodation is receiving constant attention.

Water Shortage.

Mr. LONGBOTTOM asked the Minister of Health if his attention had been called to the serious shortage in water-supplies; and what steps he proposed to take to temporarily amend the regulations regarding compensation water to riparian owners so that local authorities might be helped to overcome their difficulties during this time of emergency.—Mr. GREENWOOD replied: My attention has been drawn to this matter. In the memorandum on water shortage which I have issued this week, I have advised that, where shortage exists or is threatened, and compensation water is supplied, the water undertakers should enter into immediate negotiations with the riparian interests with the object of securing agreement for the temporary reduction or intermission of discharges of compensation water. I trust that all interests will recognise that in the present exceptional emergency, essential domestic needs must have the first consideration, and that reasonable concessions immediately may be the only way to avoid a very serious situation within a short time.

Street Noises and Public Health.

Mr. FREEMAN asked the Minister of Health whether he was aware of the increase of street noises, particularly in London, caused mainly by traffic, inflicting considerable suffering, and being a general menace to health; and what steps, if any, he proposed to take to abate the nuisance.—Mr. MORRISON (Minister of Transport) replied: This matter was considered by a conference convened by my predecessor in October, 1928, and as a result of the recommendations contained in their report, the Motor Car (Excessive Noise) Regulations were made on June 3rd, and will come into operation on August 1st.

League Maternity Convention.

Mr. R. S. YOUNG asked the Secretary of State for Foreign Affairs if he would, at an early date, ratify the League of Nations maternity convention, which had already been ratified by nine European nations.—Miss BONDFIELD (Minister of Labour) replied: I have been asked to reply. As regards this and other International Labour Conventions which have not been ratified, it is proposed to examine each of them in the light of the existing law and practice in this country, and it is not possible as yet for me to say what action may be decided upon in any particular case.

Deposit Contributors and Insurance Benefits.

Sir CHARLES CAYZER asked the Minister of Health whether his attention had been called to the position of deposit contributors to the national health insurance, and to the fact that these contributors could not receive dental or optical treatment, while in the cases of those who had been rejected by an approved society through no fault of their own, and often as a result of war service, they needed such assistance more than the ordinary members of the community; and whether he proposed to consider the general improvement of their condition.—Mr. GREENWOOD replied: The position of deposit contributors as regards title to benefits under the National Health Insurance Acts is as stated by the hon. Member. Deposit contributors who can show that they were unable by reason of ill-health to secure admission to an approved society are now, however, entitled to receive the ordinary benefits without limitation to the amount standing to their individual credit, and I consider that the guaranteeing of these benefits is the best method of meeting the needs of this class of insured persons out of the limited funds available. Men discharged in ill-health from the forces of the Crown can be admitted to the Navy, Army, and Air Force Insurance Fund, and become entitled, in addition to the ordinary benefits, to dental and ophthalmic benefits free of cost.

Small-pox Hospitals.

Mr. BEAUMONT asked the Minister of Health if he would state in which counties there were small-pox hospitals; what provision was made for dealing with small-pox outbreaks in counties which had no such hospitals; and whether it was the policy of the Ministry to encourage county small-pox hospitals as the best and most economical method of dealing with outbreaks.—Mr. GREENWOOD replied: Small-pox hospital accommodation has been provided in every county with the exception of two in England and one in Wales. In these three counties arrangements have been made for the treatment of such cases of small-pox as may occur in hospitals situated in adjoining counties. With modern means of transport there are undoubted advantages in providing small-pox hospitals to serve wide areas, and for this purpose it is often convenient that the accommodation should be provided by the county council.

Venereal Disease Clinics.

Dr. MORGAN asked the Minister of Health the total number of venereal diseases clinics at present in Great Britain and the number administered by municipalities; the total number of new cases since Jan. 1st last, and the total number of attendances; and whether he was considering an extension and more adequate facilities for such treatment in the near future.—Mr. GREENWOOD replied: The total number of venereal diseases clinics approved by my department in England and Wales is now 188, of which 60 are administered directly by local authorities. No information is at present available in regard to the second part of the question, but during the year 1928 the total number of new cases dealt with at these clinics was 85,908, of whom 27,507 were found not to be suffering from venereal disease, and the total number of attendances of patients was 2,422,749. A number of proposals for the provision of new clinics, or for the extension and improvement of the present facilities for treatment, have been approved or are now under consideration.

Panel Practitioners' Prescriptions.

Mr. REMER asked the Minister of Health if his attention had been called to the prescribing of Dr. Tomlinson, of Dukinfield, and Dr. Cooper, of Altrincham; if he was aware that the Cheshire insurance committee, representing 200,000 insured people, were unanimously of the opinion that the penalties imposed by the Ministry were harsh and punitive, and likely to result in a lowering of the standard of medical benefit of insured persons; and would he state the reasons for overruling the decision of the Cheshire insurance committee.—Mr. GREENWOOD replied: I am aware of the facts in these cases, which were decided in December last, and of the views of the insurance committee on the decisions. The decisions, which rest with the Minister and not with the committee, were taken because he was satisfied that the doctors had imposed charges upon the available funds in excess of what was reasonably necessary for adequate treatment.

Phototherapy and Light Treatment.

Mr. HARRIS asked the Minister of Health whether his department had had any inquiry into the subject of phototherapy; whether he had any information as to the proof of actual physical benefits in curing to the recipient of artificial light treatment as administered by the ultraviolet lamp; and whether he would consider holding an inquiry into the efficacy of light treatment generally, especially in welfare centres.—Mr. GREENWOOD replied: Special inquiries have been made during recent years by medical officers of my department into the application of phototherapy (including artificial light) to the treatment of disease, and the results have been published in the annual reports of the chief medical officer. These observations are being continued, and I do not see any necessity for a further inquiry. As regards the second part of the question, I am advised that the best results of this form of treatment appear to have been obtained in cases of rickets and of certain forms of non-pulmonary tuberculosis.

Health of Women Teachers.

Commander SOUTHBY asked the President of the Board of Education whether he was aware that the number of women teachers who broke down in health every year between the ages of 55 and 60 was increasing; and if he would consider the introduction of a scheme whereby women teachers could be granted optional retirement to begin at the age of 55.—Sir CHARLES TREVELYAN replied: The figures in my possession do not suggest that there is any substantial increase in the number of women teachers who break down in health between the ages of 55 and 60. Provision for such cases is already made in the Teachers (Superannuation) Act, 1925, and I cannot undertake to initiate legislation to provide for optional retirement on pension at an age less than 60.

Disturbances at Antivivisection Meeting.

Mr. DAY asked the Home Secretary whether he had now received the report from the Commissioner of Police upon the incidents which happened with regard to the disturbances at the meeting of the British Union for the Abolition of Vivisection at Caxton Hall on June 20th; whether he had considered this report; and could he now make a statement upon it.—Mr. CLYNES replied: I have now received a report from the Commissioner of Police regarding the meeting in question. The duty of police who may be present at public meetings is to prevent so far as possible any breach of the peace, and no special instructions were required or given on this occasion. It must be recognised that the task of the officer in charge in such cases is often a difficult one, as precipitate action is just as likely to provoke complaint as undue delay. The Commissioner of Police is satisfied, however, after considering a large number of statements made by persons who were present, that the officer in charge of the detachments sent to this meeting committed an error of judgment in not acting sooner. The Commissioner has taken appropriate action in respect to the officer concerned, and has communicated fully with the Union named in the question.

Industrial Diseases.

Mr. MORLEY asked the Home Secretary if his attention had been called to cases of chronic fibrosis of the lungs contracted through inhaling coal dust whilst working in ships' bunkers; and if he would consider the desirability of placing this complaint on the schedule of diseases coming within the scope of the Workmen's Compensation Act.—Mr. CLYNES replied: No such cases have as yet been brought to my notice, but if any cases have come to the knowledge of the hon. Member and he will furnish me with particulars of them, I shall be glad to have the matter investigated.

Mr. PHILIP OLIVER asked the Home Secretary whether he would consider the making of an order extending the provisions of the Workmen's Compensation Acts dealing with industrial diseases to the disease of cancer of the bladder as affecting workers in aniline factories.—Mr. CLYNES replied: An order can only be made in respect of a disease which is due to the nature of the employment, and I am advised that it has not yet been definitely established that cancer of the bladder is caused by employment in aniline works. The matter is at present the subject of a research by the London Cancer Hospital, and I will consider whether any steps can be taken by my department to facilitate this investigation.

FRIDAY, JULY 19TH.

Artificial Silk Factories and Public Health.

Mr. KELLY asked the Minister of Health what complaints had been received by his department as to injury to the health of people residing in the neighbourhood of artificial silk factories.—Mr. GREENWOOD replied: I have received a number of complaints. I would refer my hon. friend to the report by the chief alkali inspector of my department on the emission of fumes from artificial silk works which was published in January last.

Conservation of National Water-supplies.

Mr. AYLES asked the Minister of Health whether, in view of the growing shortage of water and the need for conserving the national water supplies, he would have a survey made of the actual and potential supplies of the country as a whole, with a view to their effective organisation and use.—Mr. GREENWOOD replied: A survey of potential supplies would involve a great amount of detailed investigation and would by itself be of doubtful value. The most practical course is the formation of more advisory regional water committees on the lines advocated in the booklet issued by my department last October. By means of these committees not only the available supplies, but also the needs, of all the districts in the region can be ascertained and a definite policy recommended for meeting requirements over a long period. The findings of these committees can then be coördinated in the general interests, and a national policy formulated.

MONDAY, JULY 22ND.

Methyl Chloride in Refrigerators.

Commander BELLAIRS asked the Minister of Health whether he was aware that refrigerators were in use in this country using methyl chloride; and, in view of the danger to life, if any action was to be taken to prevent its use.—Mr. SHORT, Under-Secretary to the Home Office, replied: I am aware that methyl chloride is used in a number of these machines, but I have no evidence at present in my possession which would justify interference with its use. I understand that it is the practice of the makers to issue instructions with these machines, and so far as I have been able to ascertain these instructions have proved sufficient. If, however, the hon. and gallant Member has any information to the contrary, my right hon. friend will be glad to consider it.

Accommodation of Civil Service Staffs.

Mr. WILLIAM BROWN asked the First Commissioner of Works whether he was aware that certain staffs in the Office of Works and the Ministry of Health were obliged to work in sub-basements and basements much below ground level and lit in the main by artificial light; that it was now proposed also to put Board of Trade staffs in these basements, and that the chief medical officer of the Ministry of Health had reported adversely on the use of these basements for this purpose; and whether he would provide alternative accommodation and so avoid the employment of the staff under these conditions.—Mr. LANSBURY replied: A small number of the staff work, during part of the day only, in the sub-basement, which is lit by artificial light. Other staffs work in the basement courts which enjoy good natural light, and it is proposed to utilise other similar courts for Board of Trade staffs. I am informed that the chief medical officer of the Ministry of Health has not reported adversely on the use of the basement, but, on the contrary, this officer and an officer of the Medical Research Council, reported that, subject to the execution of certain works, the basement courts were quite suitable for occupation by clerical staffs. Effect has been given to the recommendations of these officers. Under ordinary circumstances I should prefer that all staffs worked above the ground level, but at present we have no other available accommodation. My hon. friend may be assured that everything possible has been done, and will continue to be done, to keep offices as light, airy and healthy as possible.

Opium in India.

Mr. CECIL WILSON asked the Secretary for India whether all the committees appointed in the autumn of 1927 by five provincial governments to inquire into the high consumption of opium in certain areas had presented their reports; whether the local government which arranged to make a similar inquiry had presented its report; what action the government of India had taken or proposes to take upon the reports; when reports not yet presented might be expected; and whether all the reports were to be published.—Mr. BENN replied: Four of the six inquiries have been completed. As soon as the remaining two are finished the government of India propose to convene a conference to collate and compare the results obtained before the local governments pass orders. The publication of each report is a matter for the local government concerned. The Bengal report has been published.

TUESDAY, JULY 23RD.

Sterilisation of Mental Deficients.

Commander BELLAIRS asked the Minister of Health whether his department had full information as to the success of measures for the sterilisation of mental deficients in Switzerland, the United States of America, and other countries; and, if not, whether he would appoint a committee to investigate the matter and the increase of this class throughout the country.—Mr. GREENWOOD replied: The department has certain information regarding the sterilisation of mental defectives in other countries; but the measures in some countries have been introduced so recently, or applied on so limited a scale, that the data at present available do not warrant any deductions from them. I am not in a position to indicate at present whether it will be practicable to initiate an investigation on the questions to which the hon. Member refers.

New Water-supply Schemes.

Sir GEORGE PENNY asked the Lord Privy Seal whether he would consider the desirability of approaching local authorities in areas likely to suffer from water shortage in the event of drought to suggest schemes for the provision of catchment areas and reservoirs, which besides proving of great utility would provide work for the unemployed.—Mr. THOMAS replied: My right hon. friend, the Minister of Health, has recently drawn the attention of local authorities to the necessity of initiating schemes for new water-supplies in advance of requirements and has emphasised the advantages of regional water committees. Approved schemes of the character indicated would be subject to the appropriate unemployment grant.

Food Council and Milk Prices.

Mr. WISE asked the President of the Board of Trade what action was being taken by the Food Council in view of the 80 to 100 per cent. margin for distribution as compared with the farmers' price, in the scheme now under consideration for fixing milk prices by the National Farmers' Union and the milk distributing interests.—Mr. W. GRAHAM replied: I understand that the Food Council will have this matter under examination at their meeting to-morrow, and I have asked them for a report.

Chemical Warfare.

Brigadier-General CLIFTON BROWN asked the Secretary for War whether the War Office had ceased all work on chemical warfare; and if he had any information as to whether similar action had been taken by America, Germany, Italy, France, or Russia.—Mr. T. SHAW replied: His Majesty's Government have declared their intention of ratifying the Geneva Gas Protocol at an early date. In the meantime no change has been made by a departure from the research work which has been for a long time in progress. It is understood that similar research work is being carried on in the countries referred to.

Closing of Unfit Dwellings in Scotland.

Dr. FORGAN asked the Secretary for Scotland whether he was aware that the closure of houses in Elderslie, Thornliebank, Neilston, and elsewhere in the county of Renfrew, represented by the medical officer of health as unfit for human habitation, is being held up by legal difficulties, and that houses which had been made the subject of closing orders were still occupied; and what steps he proposed to take to remedy these matters.—Mr. ADAMSON replied: The answer to the first and second paragraphs of the question is in the affirmative. As regards the last part I understand that out of 51 tenants affected by closing orders in the area referred to by my hon. friend, 13 have not obeyed an order to quit. In view of the poverty of those 13 tenants no proceedings for recovery of the penalty imposed by the statute have been taken. I am in consultation with the Lord Advocate as to the steps that should be taken.

Hours of Work of Juveniles.

Mr. GRAHAM WHITE asked the Home Secretary whether he had in contemplation the introduction of legislation to regulate the hours of work of juveniles in occupations in which such hours of work were at present unregulated.—Mr. SHORT, Under Secretary to the Home Office, replied: My right hon. friend has been looking into this matter and he hopes to bring proposals before Parliament, but is not able to make a more definite statement at present.

Children and Bovine Tuberculosis.

Lieut.-Colonel FREMANTLE asked the Minister of Health if he was aware that over 2000 infants died every year from bovine tuberculosis; that this was mainly conveyed by milk; that the expenditure on treatment, convalescence, and after-care of this disease in infants amounted to over £9,000,000 a year; and if he would consider the advisability of introducing measures to secure that no milk other than that free from tubercle should be given to infants attending the 3000 infant welfare centres.—Miss SUSAN LAWRENCE replied: I am not aware from what source the hon. Member obtained the figures mentioned in the first part of the question. My right hon. friend is advised that it is not possible to ascertain precisely how many infants die each year from bovine tuberculosis, but such evidence as is available suggests that the number is less than that given in the question. The answer to the second part of the question is in the affirmative. I am not aware of any information to support the figure of £9,000,000 a year mentioned in the third part of the question. As regards the last part, dried milk is supplied at the majority of infant welfare centres, and this is recommended by my department in any case in which the ordinary milk supply is of doubtful quality. A few local authorities supply tuberculin tested milk, but it would not be practicable to require such a supply in every case nor would such a requirement be justified having regard to the many available supplies of dried milk of reliable brands.

Medical News.

UNIVERSITY OF OXFORD.—At a congregation held on July 21st, the following degrees were conferred:—

D.M.—P. J. Bach, New College.

B.M.—J. C. Nicholson, New College; and W. J. Walter, Brasenose.

UNIVERSITY OF CAMBRIDGE.—At a congregation held on July 20th the following degrees were conferred:—

M.D.—E. A. B. Pritchard, W. R. F. Collis, and R. A. McCance.

M.B., B.Chir.—G. E. Lewis, F. H. McCay, C. L. Stote, C. E. Woodrow, R. W. Windle, and D. M. Stern.

M.B.—P. B. Kittel.

B.Chir.—Sagarajasekaran Tyagaraja, F. Bush, C. P. Campion, F. W. J. Wood, and C. J. Grosch.

SOCIETY OF APOTHECARIES OF LONDON.—At recent examinations the following candidates passed in the subjects indicated:—

Surgery.—C. E. P. Davies, Guy's Hosp.; W. M. Hamer, Manchester and Charing Cross Hosp.; A. Hamid, Middlesex Hosp.; C. Hortop, Guy's Hosp.; V. J. Lopez, St. Mary's Hosp.; W. McDermott, London Hosp.; K. M. Seedat, Charing Cross Hosp.; V. J. C. Vandenbosch, Louvain; and T. K. White, Bristol.

Medicine.—A. Campbell, Edinburgh; V. N. Datta, London Hosp.; A. N. De Monte, St. Mary's Hosp.; C. Parthasarthe, Birmingham; C. F. H. Quick, St. Mary's Hosp.; P. U. Rao, Charing Cross Hosp.; and A. Somerville, Sheffield.

Forensic Medicine.—V. N. Datta, London Hosp.; E. T. Garthwaite, St. Bart.'s Hosp.; J. Gordon, St. Mary's Hosp.; C. Parthasarthe, Birmingham; C. J. Poh, Edinburgh; C. F. H. Quick, St. Mary's Hosp.; and P. U. Rao, Charing Cross Hosp.

Midwifery.—A. R. Edwards, Liverpool; R. W. Goldsbrough, Leeds; P. D. Kapur, Glasgow; E. Marks, St. Mary's Hosp.; C. J. Poh, Edinburgh; S. V. S. Rao, Madras; T. G. Robinson, Guy's Hosp.; and G. W. Sturgess, St. Bart.'s Hosp.

The Diploma of the Society was granted to the following candidates, entitling them to practise medicine, surgery and midwifery: A. Campbell, V. N. Datta, C. J. Poh, C. F. H. Quick, P. U. Rao, and K. M. Seedat.

UNIVERSITY OF LONDON.—Prof. H. H. Woollard, M.D., B.S. (Melbourne), has been appointed from Sept. 1st, 1929, to the University Chair of Anatomy tenable at St. Bartholomew's Hospital Medical College. He was educated at the University of Melbourne and at University College, London. He served during the war, being mentioned in despatches, and awarded the Croix de Guerre avec palme for his services, and from 1919–23 was senior demonstrator and from 1923–27 assistant professor of anatomy at University College, London. He has held a Fellowship under the Rockefeller Foundation, and has obtained the Symington prize for anatomical research. Since 1927 he has been professor of anatomy in the University of Adelaide.

The University Studentship in Physiology for 1929–30 (value £100) has been awarded to Miss Margaret Hill, B.Sc.

Dr. E. Graham Little has been elected chairman of the Council for External Students.

At recent examinations the following candidates were successful:—

M.S. EXAMINATION.

Branch I., *Surgery.*—Ralph Brooke, Guy's Hosp.; H. I. Deitch, Middlesex Hosp.; and J. R. M. Whigham, St. Mary's Hosp.

Branch IV., *Oto-Rhino-Laryngology.*—S. A. Beards, London Hosp.: and Mildred Warde (University Medal), London (R.F.H.) Sch. of Med. for Women.

M.D. EXAMINATION.

Branch I., *Medicine.*—A. R. Balmain, Univ. of Birmingham and Middlesex Hosp.; Samuel Berman, Guy's Hosp.; M. H. C. Dyson and L. I. Henzell, Univ. Coll. Hosp.; J. C. Hoyle (University Medal), Univ. of Manchester; R. H. Knight, St. Bart.'s Hosp.; Lucy M. T. Masterman, London (R.F.H.) Sch. of Med. for Women and St. Mary's Hosp.; S. K. Montgomery, Univ. Coll. Hosp.; Thomas Robson, St. Thomas's Hosp. K. S. Smith, Middlesex Hosp.; R. G. R. West, St. Bart.'s Hosp.; and Katharine G. L. Williams, London (R.F.H.) Sch. of Med. for Women.

Branch IV., *Midwifery and Diseases of Women.*—Elaine Œnone H. Earengey, Univ. Coll. Hosp.; Phyliss V. L. Epps, and Dorothy E. Stewart, London (R.F.H.) Sch. of Med. for Women.

Branch V., *State Medicine.*—W. E. Snell, Univ. Coll. Hosp.

Branch VI., *Tropical Medicine.*—J. A. Carmen, London Hosp. and London Sch. of Hyg. and Trop. Med.

DIPLOMA IN PSYCHOLOGY.

Winifred C. P. Abraham, Bedford Coll.; Doris I. Huband, King's Coll.; Dorothy M. Lemerle, Univ. Coll.; Norah K. Satow, King's Coll.; Ethel K. Taylor Bedford Coll.; S. E. W. Taylor, London School of Economics; Clara P. Thomson and Ellen M. Walford, King's Coll.; and W. R. Watson, Univ. Coll.

DIPLOMA IN BACTERIOLOGY.

Robert McC. Burnie, R. D. Mackenzie, R. S. Marshall, and A. F. B. Standfast, London Sch. of Hyg. and Trop. Med.

UNIVERSITY OF MANCHESTER.—The following awards have been made: Sheridan Delépine Fellowship in Preventive Medicine: Lois Stent. Robert Platt Physiological Scholarship: Eli Davis. Dr. Robert Angus Smith Scholarship in Sanitary Science: Rupert Lyth. Prof. Tom Jones Exhibition in Anatomy: J. F. Heslop. Entrance Scholarship in Medicine: G. Israëls and W. C. Barber. Sidney Renshaw Prize in Physiology: C. H. Gray. Turner Medical Prize: Donal Sheehan. Dumville Surgical Prize: Donal Sheehan. Wild Prize in Pharmacology: E. D. Portman.

UNIVERSITY OF EDINBURGH.—At a graduation ceremonial on July 17th the following degrees and diplomas were conferred:—

M.D.—*G. G. Allan, *H. M. Anderson, †J. M. Bassett (*in absentia*), ‡G. I. Boyd, E. H. Brindle, †W. R. D. Fairbairn, *G. B. Flint, Alice J. Gray, J. W. Hunter, ‡C. F. W. Illingworth, *J. B. King, Shona Macvicar (*in absentia*), R. J. Matthews, W. J. F. Mayne, *K. T. Moir, J. R. Murdoch, A. M. W. Rae, ‡C. M. Seward, Alice B. S. Smith, and Florence L. Telfer.

* Commended for thesis. † Highly commended for thesis.
‡ Awarded gold medal for thesis.

M.B., Ch.B.—R. D. Aitken, Deborah M. Alcock (*in absentia*). D. M. Alston, L. W. Banks, R. F. Barbour, H. S. A. Bishop, ‖T. P. Bliss, W. J. Brandon, K. M. Brower, J. A. Burgess, J. A. P. Cameron, A. F. K. Clarkson, E. A. Cormack, Mary E. Crowley, Timothy Crowley, J. A. Cuthbert, W. S. Dalgetty, J. M. Davidson, S. O. M. Downing, E. F. J. Dunlop, T. J. Eason, M. A. B. Fenton, John Fletcher, J. M. Fosbrooke, D. A. Fowler, Donald Fraser, J. A. Gemmel, ‖W. H. Gillespie, Kamel Girgis, ‖E. L. Godfrey, George Graham-Cumming, G. M. Greig, Alexander Haddow, Robert Hardy, ‖Robert Harkness, David Harley, R. A. K. Harper, ‖C. P. Hay, Winnifred N. Henderson, Emma L. Howard, J. M. Howie, Jean M. Huggins, William Irvine, ‖James Laurie, J. K. Law, L. R. Levy, D. K. L. Lindsay, Joyce M. Lister, Sydney Livingstone, G. A. Macarthur, R. P. A. Macaulay, M. O. Macdonald, J. P. M'Gibbon, D. J. M. MacKenzie, Margaret B. M'Laren, Dileas Maclean, Archibald Macmillan, John K. Macpherson, A. G. G. Melville, J. B. Methven, A. A. Miller, Jean M. Milne, A. St. J. Moffat, Clement Muir, J. M. Muir, William Murray, Helen R. Neve, W. E. Orchard, D. S. Patton, J. R. H. Peat, Samuel Pinkinsky, L. T. Pollard, J. R. M. Read, A. I. Rosenthal, R. A. T. Rouse, R. M. Saleh, ‖Agnes Y. Savage, Walter Schlapp, V. V. Schoeman, J. M. Scott, Agnes D. Sloan, D. A. Smith, W. H. M. Smith, Richard de Soldenhoff, Bernard Stein, W. A. R. Thomson (*in absentia*). A. J. L. Turnbull, A. B. Wallace, E. J. G. Wallace, H. J. Weir, Mary M. A. Whittet, J. L. Wilkie, W. E. Willis, Jessie R. Wilson, and J. F. A. Wood.

‖ Honours.

Diploma in Radiology.—G. O. Field, A. J. G. Mackay M. J. S. Pillai, Sher Singh, Elizabeth Thompson (*all in absentia*).

The following awards of fellowships, scholarships, and prizes have been made:—

The Cameron Prize in Practical Therapeutics has been awarded to Lieut.-Colonel Sir Leonard Rogers, F.R.S., in recognition of the discoveries he has made in the treatment of several tropical diseases, and in particular in the treatment of Cholera, Amœbic Dysentery and Leprosy.

Thesis Gold Medallists: Dr. G. I. Boyd, Dr. C. F. W. Illingworth, and Dr. C. M. Seward. Ettles Scholarship and Leslie Gold Medal: Dr. James Laurie. Gunning Victoria Jubilee Prize in Chemistry: Mr. R. W. Armour, Ph.D. Allan Fellowship in Clinical Medicine and Clinical Surgery: Dr. C. P. Hay. Murchison Memorial Scholarship in Clinical Medicine: Dr. I. G. W. Hill. M'Cosh Graduate's and Medical Bursaries: Dr. R. M'K. Honey. Mouat Scholarship in the Practice of Physic: Dr. Robert Harkness. Buchanan Scholarship in Midwifery and Gynæcology: Dr. James Laurie. James Scott Scholarship in Midwifery: Dr. E. L. Godfrey. Beaney Prize in Anatomy and Surgery: Dr. E. L. Godfrey. Conan Doyle Prize: Dr. R. D. Aitken. Annandale Gold Medal in Clinical Surgery: Dr. R. F. Barbour. Murdock Brown Silver Medal in Clinical Medicine: Dr. C. P. Hay. Royal Victoria Hospital Tuberculosis Trust Gold Medal: Dr. A. G. G. Melville. Scottish Association for Medical Education of Women Prize: Dr. Agnes Y. Savage. Dorothy Gilfillan Memorial Prize: Dr. Agnes Y. Savage. Wightman Prize in Clinical Medicine: Dr. R. D. Aitken. Pattison Prize in Clinical Surgery: Dr. J. A. P. Cameron and Dr. R. A. T. Rouse (equal). Cunningham Memorial Medal and Prize in Anatomy: C. A. Green. Whiteside Bruce Bursary: Mr. Alexander Brown.

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH.—A quarterly meeting was held on July 16th, the President, Dr. Robert A. Fleming, being in the chair. Dr. G. S. Brook, Dr. F. W. Woolrabe, Dr. A. Rae Gilchrist, and Dr. Rutherford Dow were introduced and took their seats as Fellows of the College. Dr. F. T. Bowerbank and Dr. W. T. Munro were elected Fellows of the College. Dr. S. A. Kinnier Wilson had been appointed Morison Lecturer for 1930.

ROYAL COLLEGE OF SURGEONS OF EDINBURGH.—The following candidates have passed the final professional examination for the diploma of L.D.S.:—

W. C. Craig, R. T. [illegible], A. A. McNish, J. D. Johnstone and J. N. K. Clarkson.

Pathology, Medicine, and Surgery.—W. P. Neilson.

Dental Subjects.—W. A. E. Duncan and G. M. S. McGibbon.

DONATIONS AND BEQUESTS.—Among other bequests the late Mr. John Hughes, of The Lache, Clifton Park, Birkenhead, left £1000 to the Birkenhead and Wirral Children's Hospital for a John Stanley Hughes Cot Fund; and £1000 to the Birkenhead and Borough Hospital, of which the income is to be applied for the maintenance of the hospital.—The late Mrs. Caroline Tremlett, of Highlands, Exeter, left £500 each to the Royal Devon and Exeter Hospital, the Convalescent Home, Exmouth, and the Institution for the Blind, St. David's Hill, Exeter, as well as other charitable bequests.

BRITISH SOCIAL HYGIENE COUNCIL.—The Summer School, the fourth of its kind, which is in session at Westminster College, Cambridge, remains open until Thursday, August 1st. Social problems affecting standards of sex conduct are being considered in relation to the biological sciences; on the preventive side the protective education of young people in industry and the special problem of the adolescent unemployed, the coöperation between parent and teacher in the training of children, come under discussion. Dr. F. A. E. Crew, professor of animal genetics at the University of Edinburgh, is giving a course of six lectures on Biology and Human Affairs, and Col. P. S. Lelean, professor of public health at the same University, a course on Public Health and Social Hygiene. Evening meetings to be followed by discussion will be addressed by Dr. I. Feldman, Miss V. D. Swaisland, B.Sc., Sir Basil Blackett, Mrs. C. Neville Rolfe, and Mr. P. G. Cam ray, director of Messrs. Stanley Jay, Ltd. A course in evolutionary biology, with special reference to work in school classes, with practical work, will be given under the supervision of Dr. E. Watkin at the West Riding of Yorkshire Education Committee's Summer School at Bingley from July 31st to August 14th.

Naval Medical Compassionate Fund.—At the quarterly meeting of the directors, held on 3rd July, Surgeon Vice-Admiral Arthur Gaskell, C.B., Medical Director General of the Navy, in the chair, the sum of £40 was distributed to the only applicant.

New Wing to Hitchin Hospital.—On Saturday last the Duchess of York opened a new wing of the North Hertfordshire and South Bedfordshire Hospital at Hitchin. Since the war £35,000 has been spent on the enlargement and the development of the institution, and the new wing has cost £7000.

East Sussex Hospital.—A new children's ward in the Royal East Sussex Hospital at Hastings has been opened by Lord Rothermere, who marked the occasion by a gift of 2000 guineas. The ward is the gift of Mrs. Whitefoord, of Battle, in memory of her son, Esmond.

London Foot Hospital.—This institution has just moved into new quarters in Fitzroy-square, and an appeal is being made for £12,800 to free it from debt. Last year free treatment was given to over 12,000 patients, and Sir A. Henry McMahon, the chairman, states that the number could be doubled this year if more money were available.

Post-graduate Course in Orthopædic Surgery.—A special two weeks' course will be held at the Royal National Orthopædic Hospital from Nov. 18th to 30th. Lectures and demonstrations will be given and those taking the course will have access to operations and the practice of the hospital. Application should be made to the Secretary of the hospital, or to the Secretary, Fellowship of Medicine, 1, Wimpole-street, London, W.1.

Medical Tour in Czecho-Slovakia.—A tour of the principal towns of Czecho-Slovakia has been arranged between Sept. 8th and Sept. 17th, 1929. The party will meet at Eger on Sept. 8th and will proceed to Franzensbad, Marienbad, Carlsbad, Jachymov, and Prague, where a stay of two days will be made. Macocha and Pistiany will then be visited and the party will reach Vienna on Sept. 17th. Further particulars and a detailed programme can be obtained from the organisers of the tour, Mon Voyage Société de Voyages Internationaux, 9, Rue de la Michodière, Paris, 2°.

Metropolitan Asylums Board.—Dr. E. W. Todd, D.P.H., has been appointed bacteriologist at the antitoxin establishment of the Board at the Belmont laboratories, Sutton, Surrey, of which Dr. R. G. White is the director. Dr. Todd is at present research assistant in the inoculation department, St. Mary's Hospital, a position which he has held since January, 1924, and has had eight years' experience in pathological work, including a Rockefeller Medical Fellowship held at the Rockefeller Institute in 1927–28.

Enlargement of Stornoway Hospital.—Mrs. Macaulay, of Montreal, Canada, recently opened a new wing of the Lewis Hospital, Stornoway. The wing, which consists of two maternity wards, with accommodation for nurses, has been given by her husband, Mr. T. B. Macaulay, President of the Sun Life Assurance Co. of Canada, who has endowed the hospital with the sum of £16,000. The endowment fund has just been increased by a gift of £3000 from Mr. John Bain, of Chicago, a brother of the Provost of Stornoway.

Birmingham Hospitals' Contributory Scheme.—The remarkable success of this scheme grows progressively. Since it came into operation in January, 1928, it has paid £165,000 to the Birmingham hospitals, nursing societies, and kindred institutions; there are 270,000 members employed by 4400 firms, 2500 of which add 25 per cent. to the amounts contributed at their works.

A "Sunshine" Convalescent Home.—Recently Prince George opened the first wing of a new Children's "Sunshine" Convalescent Home at Shoeburyness.

Motoring and Excessive Noise.—The regulations prohibiting excessive noise in the use of motor cars, of which notice was given by the Minister of Transport on June 3rd, are to come into force next Thursday, Aug. 1st. These regulations make it an offence for any person to use, or permit to be used, a motor car, or a trailer drawn by a motor car, which causes any excessive noise as a result of any defect in design or construction, or lack of repair or faulty adjustment. It is also an offence under the regulations to use a vehicle or trailer which makes an excessive noise due to the faulty packing or adjustment of the load.

Medical Diary.

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, London, W.

All Saints' Hospital, Vauxhall Bridge-road, S.W. Special Course in Urology, Afternoons and Evenings, duration of course one month from July 29th. Further information from the Fellowship of Medicine.

NORTH-EAST LONDON POST-GRADUATE COLLEGE. Prince of Wales's General Hospital, Tottenham, N.

Monday, July 29th.—2.30 to 5 p.m.: Medical, Surgical and Gynæcological Clinics. Operations.

Tuesday.—2.30 to 5 p.m.: Medical, Surgical, Ear, Nose and Throat Clinics. Operations.

Wednesday.—2.30 to 5 p.m.: Medical, Skin, and Eye Clinics. Operations.

Thursday, August 1st.—11.30 a.m.: Dental Clinics. 2.30 to 5 p.m.: Medical, Surgical, Nose, Throat, and Ear Clinics. Operations.

Friday.—10.30 a.m.: Throat, Nose and Ear Clinics. 2.30 to 5 p.m.: Surgical, Medical, and Children's Diseases Clinics. Operations.

Appointments.

Fletcher, T., M.B., Ch.B. Glasg., has been appointed Surgeon under the Factory and Workshop Acts for Kirkcowan, Wigtown.

Vacancies.

For further information refer to the advertisement columns.

Aberdeen, County of, P.H. Dept.—Jun. Asst. M.O.H. £500.
Barnsley, Beckett Hospital and Dispensary.—Jun. H.S. £140.
Birkenhead General Hospital.—Cas. S. £100.
Birmingham and Midland Eye Hospital, Church-street.—Res. Surg. O. Also Two H.S.'s. £150 and £110 respectively.
Birmingham Children's Hospital.—Res. M.O., £175.
Bradford Children's Hospital.—H.S. Also H.P. Each £120.
Brighton, Royal Sussex County Hospital.—H.S. £150.
Cairo, Egyptian University.—Prof. of Clinical Pathology. £E.1500.
Colonial Medical Services.—Vacancies.
Coventry and Warwickshire Hospital.—Res. H.S. £125.
Croydon Mental Hospital, Upper Warlingham.—Second Asst. M.O. £350.
Exeter, Royal Devon and Exeter Hospital.—Asst. H.S. At rate of £100.
Glasgow Royal Cancer Hospital.—Pathologist. £100—£500.
Great Yarmouth General Hospital.—Sen. H.S. £150.
Hertfordshire County Council.—Two School Dentists. Each £500.
Huddersfield Royal Infirmary.—Jun. H.S., at rate of £150.
Hull Royal Infirmary.—Cas. H.S. At rate of £130.
Ilford Emergency Hospital.—Sen. and Jun. H.S.'s.
Indian Medical Service.—Commissions.
Infants Hospital, Vincent-square, Westminster, S.W.—H.P. at rate of £75.
Ipswich, East Suffolk and Ipswich Hospital.—H.S. At rate of £120.
Liverpool, Alder Hey Children's Hospital, West Derby.—Res. Asst. M.O. £200.
Liverpool and District Hospital for Diseases of the Heart.—H.P. At rate of 50 guineas.
Liverpool County Borough.—Jun. Asst. School M.O. £600.
Liverpool Open Air Hospital for Children, Leasowe.—Jun. Res. M.O. At rate of £200.
London Female Lock Hospital, 283, Harrow-road, W.—H.S. At rate of £150.
London Temperance Hospital, Hampstead-road, N.W.—Cas. O. At rate of £120.
Longton Hospital, Stoke-on-Trent.—H.S. £120.
Lowestoft and North Suffolk Hospital.—H.S. £120.
Manchester, Ancoats Hospital.—Orthopædic H.S. Also H.P. Each at rate of £100.
Manchester Royal Infirmary.—Jun. Asst. M.O. for Radiological Dept., £350. Also Jun. H.S. £100.
Miller General Hospital, Greenwich-road, S.E.—Hon. P. to Skin Dept. Also Cas. O. At rate of £150.
Nottingham City Education Committee.—Sen. Asst. School M.O. £600.
Oldham Royal Infirmary.—Three H.S.'s. Each at rate of £75.
Philadelphia, Hospital of the Women's Medical College.—Hospital Resident.

Plymouth, City and Port of.—Asst. M.O.H. £600.

Plymouth, Udal Torre Sanatorium, Yelverton.—Res. M.O. £450.

Preston and County of Lancaster, Queen Victoria Royal Infirmary. H.S. £150.

Queen Mary's Hospital for the East End.—Hon. Asst. Radiologist.

Radcliffe-on-Trent, Notts County Mental Hospital.—Sen. Asst. M.O., &c. £520.

Rotherham, County Borough of.—Deputy M.O.H., &c. £650.

St. John's Hospital, Lewisham, S.E.—Res. House Appointment, £100.

Salisbury General Infirmary.—Res. H.P. £150.

Salisbury Municipality, S. Rhodesia.—M.O.H. £900.

Sheffield Royal Hospital.—Ophthalmic H.S. At rate of £80.

Sheffield Royal Infirmary.—Surg. Reg. £200. Also Asst. Cas. O. H.S., Ophth. H.S., and Asst. Ophth. H.S. Each at rate of £80.

University College Hospital, Gower-street, W.C.—Asst. Radiologist. £200.

Warrington Infirmary and Dispensary.—3rd Resident. At rate of £150.

Woolwich and District War Memorial Hospital, Shooters' Hill, S.E.—Jun. H.S. At rate of £125.

Worcester General Hospital.—Sen. and Jun. Res. M.O.'s. £180 and £120, respectively.

The Chief Inspector of Factories announces vacancies for Certifying Factory Surgeons at Banchory (Kincardineshire), Chipping Sodbury (Gloucestershire), at Harlow (Essex), and at Colwyn Bay (Denbighshire).

Births, Marriages, and Deaths.

BIRTHS.

Ennion.—On July 16th, at Harlech House, Burwell, the wife of Dr. E. A. R. Ennion, of a daughter.

Franklin.—On July 15th, at Banbury-road, Oxford, the wife of Dr. K. J. Franklin, of a daughter.

Harvey-Kelly.—On July 17th, at Clonhugh, Co. Westmeath, to Sybil Harvey-Kelly, M.B., B.S., D.P.H., wife of Lieut.-Colonel Charles Harvey-Kelly, D.S.O.—a daughter.

Kitcat.—On July 16th, the wife of Dr. C. de Winton Kitcat, St. Leonards-on-Sea, of a son.

Reynolds.—On July 18th, at Aldershot, the wife of Major W. L. E. Reynolds, M.C., R.A.M.C., of a daughter.

Wallace.—On July 16th, at Murrayfield, Horsham, Sussex, the wife of John Hugh Wallace, L.D.S., of a son.

MARRIAGES.

Abbot-Anderson—Porter.—On July 17th, at the Parish Church, St. Michael the Archangel, Lyme Regis, Dorset, William Maurice Abbot-Anderson, C.V.O., M.B., B.S., to Muriel Violet, only daughter of the late Mr. Percy Charles Porter and Mrs. Porter, of Abercorn-place, N.W.

Bowers—Baker.—On July 16th, at Holy Trinity Church, Brompton, Captain George Percy Farmar Bowers, I.M.S., to Winsome Mary Bassett, younger daughter of the late Mr. and Mrs. Frank Edwin Baker, of Northampton.

Osborne—Hall.—On July 17th, at St. Nicolas and St. Faith, Saltash, Surgeon-Lieutenant L. B. Osborne, R.N., of Bexhill, to Marie Kenley Hall, of Saltash, Cornwall.

DEATHS.

Beale.—On July 12th, at Roman Tower, Broadstone, Dorset, Hanway Richard Beale, M.D. (Lond.), M.B., M.R.C.S., L.R.C.P., D.P.H. (Sheffield), of Bridgegate House, Retford, Notts.

Johnson.—On July 17th, at Church-road, Hove, Sydney Perrins Johnson, L.D.S., R.C.S., Ireland, in his 74th year.

Parker.—On July 15th, at Thames View Cottage, Flackwell Heath, Bucks, George Dines Parker, M.R.C.S., L.R.C.P., M.B. Lond., aged 64.

Whitton.—On Friday, July 19th, at a nursing home, Aberdeen, Dr. Alfred Bell Whitton, Towie House, Turriff, and late of Aberchirder.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Comments, and Abstracts.

FOUR MILLENNIUMS OF CHINESE MEDICINE.

By K. C. WONG.

Part II.—The Historical or Classical Period (*continued*).

Three Great Pioneers.

Chinese medicine begins properly in the Han Dynasty and its scientific advancement centres in the figures of Tsang Kung, Chang Chung King, and Hua To—three of the greatest Chinese doctors of China. Tsang Kung, who lived about 170 B.C., was the first to record personal observations of clinical cases; a detailed list is extant of a group of his case-histories, revealing the medical philosophy of the time Of the 25 cases he has left on record—almost the only record of its kind for the next 1500 years—ten are reported as fatal. Tsang Kung was modest, for he admitted that his prognosis was not always accurate and that he could not cure any disease unless the pulse indications were favourable. He kept his case-notes for a double purpose—to estimate the percentage of failures and successes and to guide him in future predictions. The case-histories are not to be compared with those of Hippocrates—indeed, they are not of much scientific value, and after Tsang Kung this practice of taking clinical case-histories died out until the Sung Dynasty, when it was resumed fervently, and, of course, continues to be the method of the present time.

Chang Chung-King, the greatest of the trio, was also a doctor of literature. Little is known of his life except that about A.D. 195 he was Mayor of Changsha for some time, but he is often spoken of as the Chinese Hippocrates and is venerated as a sage. His fame rests chiefly on his work upon typhoid fever, which is one of the medical classics, ranking with Huan Ti's Canon of Medicine in importance. It was the first book of the kind in Chinese, but does not, as the title implies, deal with typhoid only, but with other fevers as well. In it are found 113 prescriptions, scientifically written, and containing only a few potent drugs, instead of being the "shot gun" formulæ of later practice, containing perhaps a dozen inert ingredients. Chang Chung-King was perhaps the first to employ enema to evacuate the bowels, and his antipyretic treatment of fever by cold baths antedates James Currie's method by 1700 years. Treatment which was chiefly confined to acupuncture, moxa, massage, and the administration of draughts and medical writings which were entirely philosophical, underwent change with the advent of Chang Chung-King. A new era was inaugurated and diseases were studied from a clinical standpoint, emphasis being laid on the physical signs, the symptoms, and the course of an illness; the methods of treatment and the action of drugs were studied rather than the theories of disease. Chang Chung-King stands above the crowd not only on account of his keen powers of observation but also because of his lofty ideals. He gave to the profession of medicine a high conception of its dignity and mission. But after his death scientific medicine degenerated again into dogmatic formalism, and no writings of any value or originality appeared until the Sung Dynasty, a gap of nearly one thousand years.

The last of the trio, and a contemporary of Chang Chung-King, was Hua To, the most famous surgeon of China. To him is usually attributed the discovery of anæsthetics, though Pien Chiao is credited with having employed it about four hundred years before him. It is said that he administered to his patients an effervescing powder in wine which produced complete unconsciousness, and that he performed all sorts of operations ranging from venesection and acupuncture to laparotomy, excision of the spleen, and various operations on the intestines and liver. A pioneer of hydrotherapy, he was also an exponent of systematic exercise and invented a system called the "frolics of the five animals." Most of the nobles of that period were his patients. Among them was Kwang Kung, a famous general, now deified as the god of war, on whom he operated without an anæsthetic for a poisoned arrow wound of the arm. King Tso Tso was another of his patrons. Hua To offered to cure the King's headaches by opening the skull under hashish. Accordingly he was arrested, thrown into prison, and later was executed. Just before his death he offered his manuscripts to a warder, who dared not take them, when Hua To burnt them. Legend, however, has it that a few leaves of his written work were recovered from the ashes, and that these described the method of castration, which is the only operation still known to the Chinese. The books extant bearing his name are two—viz., "Inner

Reflection Diagrams," and "The Internal Organs," and in the latter is a prescription which marks the earliest occurrence of the internal use of mercury in therapeutics.

The Four Methods of Diagnosis.

A prominent feature in this age of science was the introduction of the four methods of diagnosis—namely, observation, auscultation, interrogation, and palpation, but in course of time the first three methods fell into disuse, entire reliance being placed on palpation. The greatest importance was attached to this procedure, and it came to be believed *that any internal diseases can be revealed by feeling the* pulse alone. The supposed sympathy that exists between the different points and the pulse and the internal organs are set down in the following table:—

		Left wrist.	*Right wrist.*
Inch when lightly pressed	indicates the state of the	small intestines.	large intestines.
,, ,, heavily ,,		heart.	lungs.
Bar ,, lightly ,,		gall-bladder.	stomach.
,, ,, heavily ,,		liver.	spleen.
Cubit ,, lightly ,,		urinary bladder.	three passages.
,, ,, heavily ,,		kidneys.	gate of life.

The last two are imaginary organs.

Alchemy.

Buddhism was introduced into China by Ming Ti in A.D. 66 with unfortunate results for science. At first making but little progress it gradually gained a firm foothold, when the Taoists, realising their declining influence and wishing to stem the tide of opposition, became active. Chang Tao-Ling, popularly known to foreigners as the Taoist pope, invented charms and incantations for the curing of diseases and, seeing the lucrative income brought in by these devices, the Buddhist monks invented their system of charms, with the result that the people were steeped in superstition.

As in Europe 1200 years later, the search for the philosopher's stone and the elixir of life reached their height during the Tang Dynasty, an age of superstition. Magicians, doctors, and alchemists were found everywhere experimenting with herbs and minerals in an attempt to discover a substance which could confer on the person drinking it everlasting beauty or life. Of 23 *rulers of this period* seven experimented with these elixirs and died from the effects, and in these vain pursuits the time, the health, and *the fortunes of thousands were wasted. Chief among the* alchemists was Koh Hung, A.D. 281–300, who wrote the famous "Handbook of Emergencies." This book contains an authentic *description of small-pox—the first in the world* —Rhazes' account, which is regarded as the earliest record, being between A.D. 880–932. Another famous doctor was Tao Hung-ching, the author of "Formulæ of Famous Physicians," which is a work on medical plants. The previous materia medica contained only 365 kinds of herbs; Tao included *in his treatise* 365 additional drugs, exactly doubling the original number.

The Literature in the Tang Period.

The most important works on medicine in the Tang Dynasty were the "Thousand Gold Remedies" (A.D. 652) and the "Medical *Secrets of an Official.*" The former is a book of 60 volumes by Sun Su-moh, a doctor of literature, who is immortalised as one of the genii. There is a supplement of 30 volumes, *containing a full* collection of incantations. The latter was compiled by Wang Chu, who was not a doctor by profession. Many formulæ for demoniacal possessions and other peculiar diseases are found scattered among its pages. It consists of 40 volumes. These two works sum up the teachings and discoveries up to that time. *Treatment forms the chief feature of* these books. In fact, they are *collections* of prescriptions and remedies corresponding to the modern system of treatment.

The *fame of Chinese* medicine during the Han and Tang Dynasties spread far and wide. It is recorded that in A.D. 600 Japan sent Dr. Fuyiwaiyi and others to study medicine in China, where *they stayed* for 16 years.

While Nelaton, in Paris, invented the catheter in 1860, in China the instrument was known in the seventh century A.D. In the "Thousand Gold Remedies" the hollow leaves of *Allium fistulosum* are recommended to be inserted into the urethra to a depth of three inches, when air is then *blown into them. One doctor mentioned* in another treatise, the "Precious Mirror of Hygiene," used an empty pig's bladder with a quill tied to it for a similar purpose, but for obvious reasons such crude technique, attended with risks, soon *fell* into disuse. *The* idea of vaccine therapy seems to have been promulgated, and an instance is recorded in which the patient's own pus was taken and injected under the skin around the original sore. Organotherapy, formerly much ridiculed and now hailed as a valuable modern discovery, was known to every Chinese housewife. The use of sheep *thyroid* for cretinism, goitre, &c., is mentioned in the sixth century. Even psychotherapeutics, so much in vogue nowadays, was practised as early as the second century B.C. in the form of charms and incanta*tions.*

III. THE MEDIÆVAL OR CONTROVERSIAL PERIOD.

The Chinese have a great reverence for authority. What the ancient authori*ties assert is* regarded as always right; the accuracy of their statements is unquestioned, and this veneration of the ancients amounts almost to a worship and is the chief cause *of the scarcity of original* writings and *the petrified fixedness of Chinese medicine.*

Literature.—In the beginnings of the Sung Dynasty a marked change is noticed. Monographs on particular diseases began to appear. The number and variety of publications in this dynasty exceed that of all the previous dynasties put together; many of them are quite original. A selected *list* of the most important works is given below.

1. Tung Keh: Treatment of Beri-beri. 2 vols. The first and only monograph on this subject.
2. Shen Chi: Care of the Aged. The earliest treatise on hygiene with special reference to the care of feeding of old people.
3. Chen Chi-Ming: Text-book of Women's *Diseases.* 24 vols. A special work on diseases peculiar to women. The first of its kind in this branch of medicine.
4. Obstetrics. 2 vols. Author unknown. This is the earliest monograph on this important subject.
5. Chen Yin: Three Causes of Diseases. 18 vols. A standard work on pathology.
6. The Fontenele. 2 vols. Anonymous. It is said that the success of Chien Yueh, the greatest doctor on children's diseases, was due to a thorough knowledge of this book, which is the earliest special treatise on diseases of infants.
7. The Copper Model. 7 vols. Also anonymous. The first practical handbook on acupuncture.
8. Li Shun: On Carbuncle. 1 vol. An interesting monograph.
9. Royal Infirmary Model Essays. 0 vols. Author unknown. It is a collection of examination papers.
10. Chang Kuo: Medical Miscellany. 10 vols. Contains much that is of interest. Useful for reference.
11. Imperial Cyclopædia of Medicine. 200 vols. Compiled under imperial orders by a staff of medical men. A remarkable work, but unfortunately most of the volumes have been lost.

The distinct features of this dynasty are the inoculation against small-pox which was discovered in 1022, the establishment of medical schools, and the holding of State medical examinations in 1068. Gradually the schools declined and *then ceased to exist* until 1280 *when they were revived* by Imperial decrees. State examinations were also discontinued for some time but reintroduced in 1317.

In the Ming Dynasty another change is noticed. The publications became controversial, attacking old writings as well as contemporary literature. Four distinct schools may be recognised. Liu Shou-Cheng propounded the theory that diseases were caused by excessive heat in the body and advocated the use of cooling medicines. Chang Tzu-Ho was famous for his "attacking" policy. He compared diseases to a foreign substance in the system which should be attacked and driven out by drastic drugs such as purgatives, *emetics, and diaphoretics. Li Tung-yuan emphasised* the importance of the spleen and stomach, and put down the causes of all diseases as due to derangements of the digestive tract. Chu Tan-chi thought that malnutrition was the root of all troubles; hence he extolled the value of tonics. These famous men are called the "Four Great Doctors of the Kin Yuan Period." Later writers, like Sih Lih-cha, Chou Hsiu-yuan, Chang Ching-yo, and others only revolved round the different schools.

Literature.—An important contribution to medical science in the Ming dynasty was the publication of the "Pen Tsao Kang Muh or Synopsis of Ancient Herbals." This is a *standard work, compiled* by Li Shi-chen, a district magistrate, who was born at Ki-chan, a town in the east of the province of Hupeh. It consists of 62 books and took the author 30 years to complete. All known works on materia medica, to the number of 41, were consulted, while references to 360 medical treatises and 591 other scientific and historical works were freely made. There were 71,000 formulas given in this work and the substances enumerated numbered 1892 kinds. These are arranged in 60 great classes under 16 orders. This treatise is one of the most popular and important books in Chinese medical literature and merits the praise accorded to it by doctors as well as laymen. The "Synopsis of *Ancient Herbal*" was published in 1590. Another valuable book is Wu Yiu-Ko's "On Plague," which is a special treatise on fevers and epidemic diseases. It contains many original observations and suggestions.

Syphilis.—In some quarters it is declared that syphilis originated from China, but this is not supported by fact. Most Chinese writers of this period maintained that it was unheard of in China till the middle of the sixteenth century and that it was introduced into Canton by Portuguese from India. These statements, though not strictly true, as there are other references recording its presence earlier than this date, show that syphilis was prevalent in the Ming Dynasty. Indeed, the descriptions of this disease were very accurate and illuminating, and in one interesting monograph written in 1631 the various manifestations and the hereditary transmission of syphilis are mentioned in full detail.

(To be concluded.)

THE LITERATURE OF FOOD INVESTIGATION.

A NEW INDEX.

THE problem of food storage is far older than human civilisation, and was successfully tackled by plants and animals before man appeared on this earth. The density of modern industrial populations has created, however, difficulties in respect of the storage and transport of food which are being overcome only by the application of scientific studies covering wide fields in the domains of chemistry, physics, biology, and engineering. The value of such scientific studies becomes clear when we realise that they alone have made it possible for us in Great Britain to purchase at a reasonable price all the year round a variety of fruits and vegetables, abundance of meat, fish, and dairy produce, including dried and condensed milks, as well as eggs and butter. But the facilities created by such investigations not only enable the urban populations of the home country to enjoy a more varied, and, in certain seasons of the year, more wholesome diet, but they help to create a vast field of enterprise in food-producing countries abroad, and are therefore of fundamental importance to us as an empire which theoretically should be capable of producing and distributing all the food its enormous populations require.

The practical importance of investigations connected even remotely with the principles and methods of food transport and storage was discussed at the Imperial Agricultural Research Conference held in 1927 and it was then decided that a list of publications dealing with such matters should be issued at regular intervals, so that those engaged in any particular branch of the work might be enabled quickly to become acquainted with what has already been accomplished in that sphere. The first of these lists has just been issued under the title of "Index to the Literature of Food Investigation," and it is proposed to continue their publication bi-annually; they are compiled by the Low Temperature Research Station of the Department of Scientific and Industrial Research at Cambridge. The preface to the present number contains a brief account of the development of modern knowledge concerning cold storage, and illustrates the necessity of detailed investigations of a vast number of points in connexion with every variety of food product. For example, egg-yolk frozen without any particular regard to the temperature conditions may undergo an irreversible change which causes it to turn into an unpalatable pasty mass; this change does not take place at temperatures above −6° C., which is therefore to be regarded as a critical temperature for egg-yolk. Critical temperatures have been found for other food substances and are of obvious commercial importance since they define the limits within which foods can be chilled. Again, it has become clear that fruits under storage conditions must be regarded as living tissues which are continuously respiring and therefore altering the percentages of oxygen and carbon dioxide in the enclosed space which they occupy; the latter factors, in conjunction with the temperature, in turn influence their rate of ripening and their liability to disease. These two examples may help to illustrate the complexity of the problems that have to be studied to ensure the delivery to the customer of food in first-class condition. This issue of the index contains references to some 700 papers, most of which have appeared during the last two years, and a brief outline of the scope of each paper is appended below the title. One of the largest sections into which the subject-matter is divided is concerned with dairy produce, and some idea of the comprehensiveness of the investigations reviewed may be obtained by noting the subjects included under this heading—namely, heat treatment and cold storage, dehydration and canning, the bacteriology of putrefaction, and methods of analysis, with subsections dealing with patent specifications. Cheese-making and butter-making are considered from various aspects which include modern methods of manufacture and studies of the conditions affecting the qualities of the final products.

It is clear that a periodical of this kind will prove of value, not only to those engaged in the production, transport, and storage of food, but also to those interested in the study of human and animal nutrition, whether from the practical or from the scientific standpoint. Copies of the index (the price of which is two shillings) may be obtained from the usual agents of H.M. Stationery Office; special arrangements have been made for its sale in the United States at the British Library of Information, French Buildings, 5, East 45th-street, New York.

OCCUPATIONAL CANCER IN COTTON WORKERS.

AN address on cancer in relation to occupation was given to a conference of Trade Union Approved Societies in Manchester, on July 16th, by Dr. S. A. Henry. He pointed out that certain classes of skin epithelioma may now be regarded definitely as occupational in origin. So far as it affected mule-spinners, the spray of mineral oil reaching the clothing of the worker was the cause in the majority of cases. The Factory Department of the Home Office had now record of 869 cases of epithelioma of the skin in cotton mule spinners; 714 (82·2 per cent.) in those who were employed as spinners when the disease was recognised, 33 (3·8 per cent.) in those who had retired from work from one to sixteen years previously, and 122 (14·0 per cent.) in ex-spinners who had passed into other occupations for periods varying from a few months to thirty years. Cotton mule spinning was sixth in the list of the occupations with the highest comparative mortality figure from all forms of cancer. The earliest age at which the disease had been recognised was 22, and the latest 77. Of the persons affected, only 1 per cent. were under 30 years of age, and 4·2 per cent were under 35 years of age. The disease did not usually occur until the person afflicted had been employed in the mule room for some considerable time. In 1911, deaths from scrotal epithelioma in mule spinners made up 9 per cent. of the number of deaths from this cause in England and Wales, in 1924 they made up 40·3 per cent. Dr. Henry also dealt with the use of various types of mineral oil, and cited Dr. Twort's recent experiments in Manchester, which showed that of all samples of oil he had examined, shale was the most likely to produce cancer. Further research into occupational cancer of the skin was urgently needed.

OBJECTIONABLE ANAEROBIOSIS.

MANY experiments on micro-organisms are conducted under anaerobic conditions, or, at least, conditions which are believed to be such. The essential sought is complete absence of oxygen, and, incidentally, of all active gases. As a counsel of perfection the use of argon might well be advised, but this does not seem to be done. In the current issue of the *Biochemical Journal* Mr. H. Nicol calls attention to a well-known but little heeded objection to the use of alkaline pyrogallol as a means of removing oxygen. The evolution of carbon monoxide when oxygen is absorbed by this reagent has long been known to occur, although the proportion formed can be kept down to amounts which are negligible for purposes of gas analysis by proper precautions. In bacteriological work it is not easy to observe these precautions, and in any case small traces of carbon monoxide may have a toxic effect on the organisms experimented with or possibly may serve as a source of oxygen. It is not of course difficult to free nitrogen from carbon monoxide, but this means the introduction of the gas into the apparatus containing the culture, and is more troublesome than the usual plan of absorption in situ. The use of oil on the surface of a liquid medium is not effective, for oils absorb oxygen from the air and allow it to pass downward to the liquid beneath.

A NEW POCKET ELECTRIC AURISCOPE.

AN auriscope which carries its own illumination and is suitable for the waistcoat pocket has been put on the market by Messrs. John Smith and Son, of Glasgow, at 32*s.* 6*d.*, who claim that it is British made throughout. The design is that of a small "fountain-pen" type of electric torch, with a dry battery in the handle; the usual bulb and reflector are removed, and a special adapter fitted, into which the auriscope plugs. This is provided with a detachable speculum, different sizes of which can be supplied and would be necessary in practice. The lens is removable, to permit of working through the speculum, and there is a second smaller lens on a swinging arm which can be brought into position without interfering with the use of a probe or paracentesis knife. The apparatus is well made and convenient for use at the bedside. It has a fault which is common to many of these instruments. The lenses focus an object at the tip of the speculum and give good definition at this level; but when the patient is being examined the membrana tympani lies about half an inch beyond the tip of the speculum and is decidedly out of focus. This defect should be remedied by an alteration of the focal length of both lenses.

INDEX TO "THE LANCET," VOL. I., 1929.

THE Index and Title-page to Vol. I., 1929, which was completed with the issue of June 29th, is now ready. A copy will be sent gratis to subscribers on receipt of a post-card addressed to the Manager of THE LANCET, 1, Bedford-street, Strand, W.C. 2. Subscribers who have not already indicated their desire to receive Indexes regularly as published should do so now.

Fifty Years
OF
DERMATOLOGY.

A MALCOLM MORRIS MEMORIAL LECTURE

Delivered on May 16th, 1929, under the Auspices of the Chadwick Trust,

BY SIR NORMAN WALKER, M.D., LL.D., F.R.C.P.,
CONSULTING PHYSICIAN FOR DISEASES OF THE SKIN TO THE ROYAL INFIRMARY, EDINBURGH.

THOSE who decided that the Malcolm Morris Memorial Lectures (of which this is the third) should be concerned alternately with dermatology and public health made a very wise and far-seeing decision. The subjects are closely interwoven, and to both of them Morris gave of his best.

I propose to sketch the progress of dermatology during the last 50 years, during most of which Malcolm Morris was an active force. When, after qualifying as a Member of the Royal College of Surgeons of England in 1870, and after a period of study in Vienna, Morris commenced practice in Goole, I question whether there were many inhabitants of the East Riding who had ever heard the word dermatology. Skin diseases were, at that period, commonly attributed to dirt (and my native country had an unenviable reputation in that respect), to some mysterious humours which no one could satisfactorily explain, or to gout, which, being a fashionable complaint of the better classes, was itself sufficient for the climbers of those days. It is so nearly 50 years since I commenced the study of medicine that I make no excuses for using that as another reason for the round figure. Nor, I think, do I need to make any when I begin these reflections with special reference to Edinburgh.

DERMATOLOGY IN EDINBURGH.

In 1880, dermatology in Edinburgh was in a state of hibernation. In the middle of the nineteenth century it had had quite an active period. Hughes Bennett, whose name is best known as a physiologist and as a physician, and to whom belongs the credit of having been the first to introduce the use of the microscope into the teaching of clinical medicine in Edinburgh, took an active interest in dermatology, and his writings on many dermatological subjects are still well worthy of perusal by even the youngest of our craft. He was not alone in his interest, for his colleague, Laycock, the Professor of Medicine, was also, to use the quaint wording of the Anatomy Act, "addicted" to dermatology. In those days, every professor in the Faculty of Medicine had the right to a share in the medical wards of the Royal Infirmary, for the purpose of giving clinical instruction to his students. But as there were not enough wards to go round there was an in-and-out arrangement, under which each took charge for periods of three months. Chance brought it about that the charge of the wards allocated to the diseases of the skin alternated between Laycock and Hughes Bennett, and I have heard from many old friends, now passed to their rest, of the enjoyment of the students who had the opportunity of going round with each when he took over charge from the other, and of hearing very candid accounts of the blunders in diagnosis and the inadequate treatment which had occurred during his absence. They had no direct followers and when I began medicine in 1880 there were no skin wards in our new Royal Infirmary. There was, however, one ward in which there were usually some skin cases. I alluded a few minutes ago to the fact that any professor in the faculty could claim opportunities for teaching clinical medicine, and that in the past these opportunities had been exercised by occupants of the chairs of botany, chemistry, anatomy, pathology, materia medica, physiology, and medical jurisprudence. In the days I speak of the last of these chairs was occupied by Sir Douglas Maclagen, a member of a famous Scottish family which supplied southerners with an Archbishop of York. Sir Douglas, before he was appointed professor, had served his time as an ordinary surgeon to the infirmary but, curiously, the privileges granted to the physicians were not extended to the surgeons. In his youth, Maclagen had spent a good deal of time in postgraduate study in Paris, then the Mecca of dermatology and, on his return to active duty as a physician in the infirmary, he filled many of his beds with skin cases, and when his turn came round to give a clinical lecture he usually selected his subject from some of them. Several of the ordinary physicians and surgeons took some interest in skin diseases and it was my good fortune to commence clinical work—as Chairman of the Examination Committee of the General Medical Council I should almost blush to confess it—in my very first year under one whose personality is known the whole world over, thanks to Sir Arthur Conan Doyle, as Sherlock Holmes. Dr. Joseph Bell was the last of a long line of Bells, surgeons in Edinburgh. To his out-patient clinics came patients with all sorts of diseases, not a few of them dermatological, and no one would have appreciated more intelligently the detective skill which Joe Bell showed in investigating these cases than Malcolm Morris. It was from Bell that I first learned to distinguish between lupus and rodent ulcer, a distinction not made and not regarded as seriously important by some of his colleagues. A happy inspiration led me to ask the clerk of the Royal College of Surgeons of Edinburgh to search the minutes of the College, and I learnt with great interest that Malcolm Morris was proposed for the Fellowship of the College in 1882 by Sir Joseph Fayrer and seconded by Dr. Joseph Bell. Morris often used jokingly to refer to the fact that a part of his success was to be attributed to the fact that, owing to his Christian name and to the fact that he was a Fellow of the Royal College of Surgeons of Edinburgh, some people assumed that he must be a Scotsman and therefore capable.

When Morris commenced practice in London the dominant personalities were Erasmus Wilson, Jonathan Hutchinson, and Tilbury Fox. In many hospitals the skin appointment—if there was one—was held by some member of the staff—usually the junior staff—in addition to his ordinary duties, and he had to make his own opportunities for investigation. I have a vivid recollection of a day spent with my old friend, Colcott Fox; we lunched at the National Liberal Club, went to Westminster Hospital at 2 o'clock, and from then until nearly 7 he saw a constant stream of patients and I know that, long before the end, my mental capacity was exhausted! Two or three students looked in at various periods during the afternoon and, no doubt, picked up some crumbs from Fox's sage comments. While much yet remains to be done, the contrast in the present day is very remarkable. It no longer remains a chance whether the person whom circumstances put in charge of the skin department was interested or whether he regarded it as a duty to be discharged in order to get back to his own job. Almost every teaching school in the country is now supplied with a well-trained dermatologist, and the students of to-day get regular, careful, systematic instruction.

My own immediate chief in Edinburgh was Allan Jamieson. He had a career interestingly like that of his friend Morris, for they met at Hebra's feet in Vienna and lit their torches at his altar. They each spent some useful years in general practice in a seaport town—as a residence, I should place Berwick-on-Tweed before Goole—and each, having spent some time in study abroad, settled as a general practitioner in the town where he was educated. In these larger fields they found more scope for their special interests. Their experience and their influence grew, and each played a notable part in forwarding the art of dermatology. Jamieson had at first one—later extended to two—out-patient days in the week and his Saturday clinics were often attended by as many as 300 just as orchid fanciers do! There did not seem to be much practical value to come out of it, and the pessimists and the cynics said many cutting things, but it directed attention to the subject and was one of the many to which Sir Malcolm devoted his energies. His book, "Ringworm in the Light of Recent Research: Pathology, Treatment, Prophylaxis," published in 1898, was an important contribution. But the most zealous organiser had a hard row to hoe! The disease was regarded as a nuisance but, as it did small harm to health, was but little considered. I heard from my mother that, when she was 10 years old, 87 years ago, she was discovered to have ringworm. She was removed from the better-class school which she was then attending, but attended, for over a year, without any difficulty being raised, what she described as the "Keelies'" school in Stockbridge! I think we owe the immense change which has come over the situation mainly to two things: the inspection of school-children, and an action of the Russian government which sent Jews and favus from Russia to London many years ago. We were painfully familiar with favus in Edinburgh, but it was the Russian immigrants who opened your eyes to its seriousness in London. The problem was almost at once realised, and the organised arrangements made at the London Hospital have restored favus in London to its old place of a curosity. One can look back from the now universal and universally approved inspection of school-children to the attitude with which it was received when it was introduced in the first decade of this century. Some of the older inspectors can still amuse us with stories of the crowds of angry mothers who waited outside the doors of the school to see the inspector. An immense amount of feeling was aroused; once, breaking a journey between London and Edinburgh to spend a night with an old assistant in the Midlands, I was invited to attend a public meeting, which was to be held that evening, with the vicar in the chair, to protest against this interference with the liberty of the subject. Some of you may be familiar with the local patriotism of our border towns; the spirit of competition between them affects everything, and when the inspector reported that the percentage of "dirty heads" in the schools in Burgh A was 54, local feeling was aroused, not at the figures, but at the fact that the same inspector reported that in Burgh B it was only 48!

After a good deal of persuasion the Edinburgh School Board established, in 1912, a special school for children affected with ringworm and favus. I remember very vividly the storm which its opening aroused. The columns of our evening papers were filled with letters of protest. It so happened that for convenience the school was established close to the Royal Infirmary and accidentally it happened to be near two of our largest public schools for boys. The correspondents drew attention to the risks that the pupils of these schools would run, and, with that tendency of newspaper correspondents to follow the mentality of the auction room, higher and higher objections were raised until one imaginative person warned the university that the risk to the students attending the infirmary would be so great that parents in the colonies would no longer send their sons to Edinburgh. When the schools was opened in January, 1912, about 60 pupils were admitted, most of whom had been absent from school for periods varying from a few months to four years; several had never been to school, [amongst them two boys 12 years old. The increasing number of cases—I draw attention to this—necessitated enlargement of the school, and three years later the next-door house was acquired and accommodation provided for 160 pupils. In the session 1920–21 290 pupils were discharged cured; the greatest number in any one session. In 1924 the numbers began to decrease rapidly and in 1926 the staff was reduced to its original number of three teachers, eight having been at one time necessary. Over 2300 children have passed through the school and now the majority of those attending are under school age. The detailed figures are instructive: 1912, 67; 1913, 97; 1914, 88; 1915, 143; 1916, 260; 1917, 262; 1918, 347; 1919, 381; 1920, 430; 1921, 402; 1922, 351; 1923, 344; 1924, 265; 1925, 214; 1926, 143; 1927, 117; 1928, 109. To-day there are only 20 pupils in the school. I have given details of this, firstly because it was under my own direct supervision, and secondly because it points the useful lesson that organised attention directed to such a disease invariably, at first, seems to increase the number of cases. What it does is to bring them to light; then a level is reached, and then the number begins to decline. It is of interest to know that the educational level attained was higher than the average in the schools under the authority, probably owing to the fact that the children got their dinner in the school and that the classes were smaller.

More striking still is the school's record of favus, a disease which used to provide from 20 to 40 new cases annually in the infirmary skin department; many of these, of course, were adults and "incurable." A year or two ago I asked our Central Education Authority to give me what information they could about the existence of the disease in Scotland and, after careful inquiry through their official channels, they reported to me that in the whole of Scotland there were 15 cases and none of them in Edinburgh. This success could not have been attained had it not been for the discovery that in X rays we had a remedy which, properly used, could be trusted to remove all the hairs from the affected scalp—diseased as well as healthy. I do not remember who was actually the first to use the rays in ringworm, but it is undoubtedly to Sabouraud that the general adoption of the method was due. Here, again, we owe an advance to the combination of laboratory and clinical methods. It was through scientific study of the fungus that the way lay to the cure of the disease. When one reflects that in the past, even in well-organised institutions, the average time required to cure the disease was over three years, and that it is now reduced to less than three months, the dermatologists need no longer smart under the gibes of their critics but may point to the thousands of years of education that have been saved in a little over 20 years.

It looks as if the X ray treatment of ringworm might, in its turn, have to give way to the thallium method. The history of thallium as a remedy is interesting. It has long been known that its administration was followed by alopecia, but it did not occur to anyone that it might possess such selective powers as to confine its action to definite areas, and it is indeed a very remarkable fact that it does so. Attempts were made to utilise its depilatory action in the treatment of ringworm quite early in this century, but were discontinued on account of the severe toxic symptoms produced. It was only in 1918 that Cicero published the results of his successful use of it in a series of cases. Since that date it has been quite extensively employed, and there are now records of over 3000 cases in which it has been proved efficacious. In the ringworm school in Edinburgh it has proved very satisfactory in shortening and simplifying treatment. The method has met with an unfortunate set-back on account of a recent calamity. The moral I draw from that is that it is unfortunate that the metric system used in the British Pharmacopœia of 1914 and long in use in all the scientific branches of medicine is so slow in spreading into practice.

While we have been prevailing in our struggle with ringworm of the scalp, another form of ringworm has made great strides in this country. I allude to the fungus infection of the skin long known in the East as dhobi itch—epidermophytosis. Many people think that the prevalence of this is a sequel of the war and, indeed, many brought home the infection with them from the East. But it had made considerable progress before the war, particularly wherever collections of young men were gathered together. The very slight symptoms which it produces are largely responsible for its spread. A little irritation of the skin of the hands or between the toes does not always send the patient to a doctor for advice; it is only when the symptoms are more severe that advice is sought. Nevertheless, the condition is all the while infectious, and I am sure that cases are becoming increasingly numerous. In a certain proportion of cases the nails become infected and I know of no fungus infection which one approaches with more respect than fungus infection of the nails. We have gone a long way to conquering ringworm of the scalp by organisation. I plead for its application to this condition! If an hour were set apart for a clinic for this malady alone I should look for the same measure of success as has been achieved in lupus, in ringworm of the scalp, in favus, and in diabetes. I think the most promising *feature of the campaign against asthma is that cases* are to be collected in clinics and studied in groups.

SCABIES, IMPETIGO, AND PEDICULOSIS.

The teacher of dermatology may, from time to time, regret the diminution of his opportunities for teaching students to become familiar with what used to be very common diseases. This is particularly true of the commonest diseases, and there is no doubt that the teacher of to-day does not have the same superabundant opportunities of demonstrating cases of scabies, impetigo, and pediculosis as his predecessors had. In my own days it was almost always possible to demonstrate to students the close relationship between impetigo and pediculosis capitis. Thanks to school inspection, all these diseases have markedly diminished. They are still numerous, but I venture to prophesy the advent of a time when the teacher of dermatology will welcome the appearance of a really good example of impetigo to demonstrate to his students.

URTICARIA, ERYTHEMA, DERMATITIS, AND ECZEMA.

With one exception, all the diseases I have dealt with fall obviously into the preventable category, for in all of them the cause is recognisable and determinable. But there remains a great mass of disease where the progress recorded, marked though it be, is not so dramatically presentable as in those already dealt with. To only two groups of these diseases have I time to refer. The first comprises the conditions known as urticaria (nettlerash), and erythema (redness), while the second includes the vast number of affections of the skin which, according to our fancy, we label "dermatitis" (inflammation of the skin), or "eczema," which is the Greek word for an eruption. It must be conceded that the labelling of a patient's ailment with one or other name does not greatly help, and it has become more and more evident that it is the cause that is important, and not the name. The one group, speaking generally, has characteristics which suggest that it arises from some internal cause, and the other, also speaking generally, rather suggests external irritation. It is along the lines of concentration on the possible cause, rather than on the appearance of the eruption, that marked progress has been made in these 50 years. It had long been known that the ingestion of certain foods—I merely instance oysters, lobsters, strawberries, and cherries—was followed in certain individuals by an outbreak of nettlerash. Some of the older authorities, in their condemnation of all fish and of all fruits, rather obscured the truth, but nevertheless there is evidence in some of their writings, and perhaps most of all in the works which, like Morris's, went through several editions, of something instinctively suspected but beyond their ken, a spirit like that of the old Athenians, who erected an altar to the Unknown God. "One man's meat is another man's poison" is an old proverb, and it is in the application of this that advance has been made. Even the oyster, perhaps the most notorious sinner, only affects a small percentage of humanity, and as one goes down the list the percentage decreases. But the list of substances to which some people react is being daily lengthened, and now that outbreaks of urticaria have been traced even to milk, it is obvious that the matter is one of importance. It is quite often possible, by starving a patient for a few days and then adding one article of diet after another, to alight on the cause, but this is often a very slow process. The hunt for the peccant article has been made much simpler by the introduction of the cutaneous tests. By their means, the sensitiveness of a particular individual to a particular substance can be at least suggested, and much time thereby saved. Some people, in my judgment, have adopted these tests too enthusiastically and expect that it will be possible to relate every case of urticaria to its cause if one only perseveres long enough. The relationship between urticaria and asthma, long remarked but little understood and not infrequently scoffed at, has been clarified by the demonstration that certain substances may produce one or other *type of reaction*. I do not wish to be thought to belittle the enthusiastic cutaneous tester; it is worth many hours of work if one can free a patient from a very troublesome symptom by simply advising him to avoid, in future, Findon haddock, some particular variety of cheese, tomatoes, chestnuts, or damson jam. There are other causes of urticaria than foods, and these must be sought with the same diligence.

I next come to that conglomerate assemblage of reactions of the skin which goes by the name of eczema. For two or three centuries authors have sought for a satisfactory definition. The fact is that it is impossible to define a condition which may be due *to any one of hundreds of causes. It is rather* remarkable that so many who sat at Hebra's feet did not carry further his researches into external causes! Their search was too often directed to some other organ of the body; eczema, it was held, had its manifestations on the skin, but the attitude was to seek for its cause anywhere rather than in the skin itself. It is to some extent unfortunate that Hebra devoted so much attention to the reaction produced on the skin by one or two irritants (notably croton oil) and assumed that all irritants would produce the same reaction. It is to the recognition of the fact that different irritants may produce apparently similar reactions in some persons, and that the same irritant may produce *different reactions in others*—in short, to a wider appreciation of the importance of idiosyncrasy—that we owe most of our recent advances. The skin and the stomach are wonderfully alike in this respect: there are a few persons who boast that they can eat anything, but most of us are aware that there are some things which agree with us better than others. So it is with the skin. There are very few who have a skin that nothing will irritate, and very few chemicals, using the word in a wide sense, which will not irritate some skin if brought into contact with it. Fifty years ago bakers' itch, bricklayers' itch, and washerwomans' itch were familiar. The work of my friend, Dr. Prosser White, on the industrial diseases of *the skin shows an imposing list of over a* hundred varieties, and we discover new ones every year. I agree with Hartzell when he says: "Many, if not most, of the cases of so-called acute eczema are, in fact, due to some plant, dye or drug with which the patient comes in contact." The search for the cause in a suspected case is an enthralling pursuit. I learned recently from Sir Harold that his father and I shared a common zest for those cases that required something of the detective instinct of Sherlock Holmes. Perhaps the most intriguing cases one has to deal with are those connected with the vegetable kingdom. The most familiar vegetable poison in this country is the Chinese primrose. It may be familiar, but it *is astonishing* how many cases one sees in enthusiastic floriculturists who are entirely ignorant of its irritant effects. No treatment, however skilfully directed, is of much use when the patient is innocently and ignorantly exposing himself to a noxious irritant.

EQUIPMENT.

The dermatologist of to-day has a vast armoury compared with that of his predecessor 50 years ago. He has scores of new weapons; some of them are very potent, and many are double-edged. Chemical and bacteriological warfare is waged against the germs which infest the skin. New remedies are showered upon us with bewildering frequency, and, if many of them have but a short career, the good ones remain. The use (and no less the abuse) of vaccines is of great importance, but they require judgment and experience in their administration and their value is best tested and estimated by those whose knowledge and practice is not limited to these new remedies. I would counsel the younger generation not altogether to neglect old remedies and the principles which lie behind their use; to clean the skin, to keep it at rest, and to let nature do the cure, is as important as ever it was. I would not give up the use of the starch poultice (which Allan Jamieson learned to use in Paris and spent all his active life in advocating) for any dozen vaccines.

It is recorded of Hughes Bennett, whose name I mentioned earlier, that he treated all his acute cases with weak alkaline soaks and all his chronic ones, as Noah did the ark, with pitch within and without. It takes years of experience to understand exactly when and how to use tar, but it and its derivatives remain among the most useful of applications.

The older dermatologists perhaps took human nature more into consideration than do some of their successors. Possibly I am speaking from the maturer mind, and human nature has changed as well as remedies. I have often followed, with benefit to the patient, the spirit of a bit of advice Malcolm Morris once gave me; we were discussing the advantages and the rather manifest disadvantages of chrysarobin in the treatment of alopecia areata and the importance of interesting the patient in the treatment to be used. Morris said: "Instead of the conventional ointment or lotion I sometimes find it helpful in this condition to advise patients to cut a lemon in two, to sprinkle the cut surface with Goa powder and rub the part. If I am anxious to make the patient specially attentive to the treatment I advise him that limes are even better than lemons."

If I were to endeavour to find an explanation for the advance I would put it on four grounds:—

1. The improvement in school education; we get better-trained students than our predecessor did. I do not refer to the geniuses of the past or present, but to the average level.

2. The marked improvement in medical education and, not least, the introduction to what our American friends call the fundamental subjects. The students of to-day are far better grounded in chemistry, physics, biology, physiology, pathology, bacteriology, and pharmacology than we were, and are a more receptive soil for sowing the seed of the advances in medicine and surgery and their branches.

3. Next I would put research; everyone recognises the importance of research in every branch; in every laboratory and in every large hospital it is constantly going on, either as some special research or as an integral part of properly done routine work. Not the least important factor in the advance is the increasing combination between the clinician and the laboratory worker. I have no sympathy with and little belief in the assertion that these are two rival camps. Here and there it may be true that a narrow-minded individualist in a laboratory regards all other than laboratory workers as mere children at play, and here and there clinicians are still prepared to back their "clinical instinct" against any laboratory finding. But these are exceptions, and in all active centres throughout the world there is closer and closer combination between the two branches and, as the results continue to show the advantages of coöperation, it may be prophesied that the exceptions will get fewer and fewer.

4. Then there is coöperation. Special departments no longer work in little water-tight compartments. They touch, on the one side, their medical colleagues on the staff, and on the other those public authorities who are responsible for the health of the community. I have not, I think, stinted my expression of appreciation of what the community owes to the inspection of school-children. School-children are not the only class who would benefit from closer coöperation and organisation. Not long ago I had the pleasure and satisfaction of participating in an organised inquiry into a disease of the skin which had been known for over half a century to attack certain workers in the shale oil industry. The combination of the Home Office, an exceedingly capable local doctor, and an expert, was able to suggest a method which, in a few months, practically abolished a condition which meant suffering to many and death to some. In the reorganisation of local government, now in train, there is much hope that such methods will spread.

The dermatologist of the future has a wide field before him. He must come to it well equipped. Some used to argue that he should approach it through ten years of general practice, as Malcolm Morris and Allan Jamieson did. Here is a description of his qualifications from America: "He must of necessity be an internist (physician) and pathologist—if such a thing is possible, a better-trained internist than the internist himself. He must be a bacteriologist, a physiologist, an embryologist, and a physicist." That is the American ideal. Translated into our more practical form, it means that he must be thoroughly trained in all these subjects, and be capable of appreciating the work done by the experts in each and of applying such of it as is applicable to his own special work.

I close, in the spirit of what I have tried to make the theme of this lecture, with a quotation which I believe would have been appreciated by the man whose memory we recall to-day. As befits the son of a Scottish manse, I take it from the Bible and I think you will agree not inappropriately, from the Book of Job. There, in verses 15 and 16 of the twenty-ninth chapter, you will find these words: "I was eyes to the blind, and feet I was to the lame. I was a father to the poor, *and the cause I knew not I searched out.*"

A CONTRIBUTION TO THE STUDY OF RENAL GLYCOSURIA.

By A. MUIR CRAWFORD, M.D., F.R.F.P.S. Glasg.,
ASSISTANT PHYSICIAN, ROYAL INFIRMARY, GLASGOW.

WHEN a reducing substance is found in the urine two questions naturally arise: (1) Is the reducing substance glucose? (2) Is the patient affected with true diabetes mellitus? To the first question a satisfactory answer can usually be given by carrying out the phenylhydrazine and fermentation tests for glucose. To the second question an affirmative answer may be given when the history and symptomatology are sufficiently characteristic; a negative answer, on the other hand, can only be given after careful investigation.

Glycosuria is said to be relatively uncommon and although its incidence may possibly vary in different classes of society, there can be little doubt that the excretion of glucose in the urine is more common than is generally supposed. This may be partly due to the not uncommon practice of requesting or accepting for routine examination a morning specimen of urine—that is, one passed after several hours' fast. It is obvious, therefore, that the accidental discovery of glucose in the urine of a patient who has no definite diabetic symptoms demands a careful investigation of the cause of the abnormality, since it is well known that a certain proportion of glycosuric patients are not true diabetics.

Of the conditions included in the group of non-diabetic glycosurias an important one is renal glycosuria, now recognised as a distinct clinical entity. A considerable amount of literature has already appeared on the subject, and various other names have been applied to this interesting anomaly, names such as "diabetes innocens," "glycosuria without hyperglycæmia," and "negligible glycosuria," all of which may be regarded as synonymous.

Joslin[1] defines renal glycosuria as "a persistent glycosuria which is relatively independent of the diet, and in which there is absence of hyperglycæmia as well as of the symptoms of diabetes." Graham,[2] in 1916, described two types: the common one, in which less than 10 g. of sugar were excreted daily, and another type in which 10 to 30 g. were excreted. In 1923 he described another type[3] in which no sugar is detected in the urine when the patient *abstains from food for a short time*, but sugar is excreted when carbohydrates are eaten. This type he regarded as a link between normal people and patients with a typical renal glycosuria. Many other cases, of varying type and severity, have been published. Leyton[4] records 18 cases of which 7 had histories of glycosuria averaging 18 years. Garrod,[5] MacLean,[6] and Graham,[2] [3] record numerous cases, and several papers have appeared, chiefly in American journals, describing cases in which glycosuria only appeared after a meal (Goto,[7] Strouse,[8] Murlin and Niles,[9] Lothrow,[10] John,[11] Goto and Kuno[12]).

Normally the kidney does not excrete glucose so long as the concentration of blood-sugar remains below 0·18 per cent. and this figure is generally accepted as the normal renal threshold for glucose. In renal glycosuria the threshold for glucose is lowered; it may be slightly, moderately, or greatly below the normal, and the kidney continues to excrete glucose so long as the blood-sugar concentration remains above the threshold level. Persistent glycosuria is not, therefore, a sine qua non in the diagnosis of renal glycosuria; and furthermore, in a certain number of cases the glycosuria is not relatively independent of the diet, but is, in reality, dependent upon it. Joslin's definition, therefore, is only applicable to certain cases. An important question thus arises, whether the different types of renal glycosuria are merely varying degrees of one type of abnormality, the variation depending upon the degree to which the kidney leak-point is removed from the normal, or whether they represent abnormal states differing in nature and ætiology.

FIG. 1.

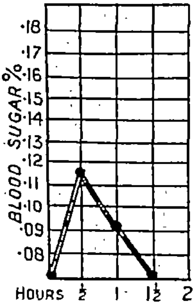

FIG. 2.

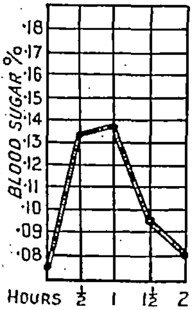

It is generally stated that renal glycosuria is more or less harmless and requires no treatment. The study of the condition, however, brings to light certain problems which demand further elucidation. These problems have occurred to me in the course of a personal investigation and will be discussed after a brief description of six cases.

Clinical Histories.

CASE 1.—Male, aged 39, complained of feeling "over-strung" and nervous, due in his opinion to overwork. A general physical examination proved negative, with the exception of a slightly increased blood pressure, the figures being: systolic 150, diastolic 85. The Wassermann reaction was negative. The urine, however, contained a fair amount of glucose. Further investigation showed the morning urine (fasting) to be sugar-free, while the *urine passed an hour and a half after a mixed meal contained* a fair amount of glucose. A glucose tolerance test (50 g. of glucose) showed the blood-sugar curve to be not only well within normal limits, but abnormally low (Fig. 1). At the beginning of the test (fasting) the urine was sugar-free, while at the end of the test there was a moderate glycosuria.

CASE 2.—Male, aged 25, complained of general weakness, irritable temper, and headaches of four months' duration. A general physical examination proved negative. The urine, however, was found to contain glucose. A glucose tolerance test (50 g. of glucose) showed the blood-sugar curve to be well within normal limits (Fig. 2). At the beginning of the test (fasting) the urine contained a trace of glucose, while at the end of the test it contained 2 per cent.

CASE 3.—Female, aged 30, complained of attacks of tinnitus and giddiness accompanied at times by nausea and vomiting. She had been examined by an aurist, who formed the opinion that the symptoms were not due to any aural disease. The symptoms first appeared after a long period of harassing work and mental strain. The patient was debilitated and neurasthenic and her urine was found to contain a small quantity of glucose. Further investigation showed the morning urine (fasting) to be sugar-free, while the urine passed an hour and a half after a mixed meal contained a moderate amount of glucose. A glucose tolerance test (50 g. of glucose) showed the blood-sugar curve to *be well within normal limits (Fig. 3), but* at the end of the test the urine contained a small quantity of glucose. In this patient the troublesome symptoms disappeared after a prolonged holiday and it was then noted that a carbohydrate meal failed to produce glycosuria.

FIG. 3.

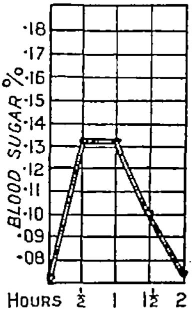

FIG. 4.

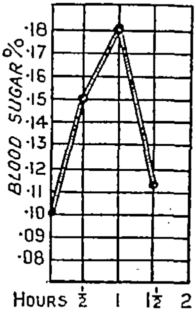

CASE 4.—Male, aged 48, complained of headache, insomnia, weakness, and loss of weight. He was much engrossed in business and believed his symptoms to be due to worry. Examination showed a moderate degree of arterio-sclerosis. The systolic blood pressure was 148; the diastolic 90. The Wassermann reaction was negative. The urine was *found to contain* a moderate amount of glucose. Further investigation showed the morning urine (fasting) to be sugar-free, while the urine passed two hours after a carbohydrate meal contained 1·3 per cent. of glucose. A glucose tolerance test (50 g. of glucose) showed a normal curve (Fig. 4). At the beginning of the test (fasting) the urine was sugar-free. Half an hour after the administration of the glucose the blood-sugar had risen to 0·15 per cent. and the urine contained 0·63 per cent. of glucose. At one hour, when the blood-sugar had risen to 0·181 per cent., the urine contained 1·18 per cent. of glucose. At two hours the blood-sugar had dropped to the starting level of 0·1 per cent. and the urine then contained only a trace of glucose.

CASE 5.—Male, aged 51, was rejected at a life insurance examination on account of glycosuria, the urine being found to contain 0·9 per cent. of glucose. He was a well-developed, healthy looking man and felt in excellent health. A morning specimen of urine (fasting) was found to be sugar-free, while the urine passed two hours after a mixed meal contained a definite but small quantity of glucose. A glucose tolerance test (50 g. of glucose) showed a normal curve (Fig. 5), but one hour after the administration of the glucose, when the blood-sugar had reached a level of 0·168 per cent., the urine contained 1·25 per cent. glucose.

CASE 6.—Male, aged 40, was rejected at a life examination on account of glycosuria. He appeared to be in perfect health. A glucose tolerance test (50 g. of glucose) showed a curve suggestive of early diabetes, but with a definitely lowered renal threshold (Fig. 6). At the beginning of the test (fasting) the urine was sugar-free. Half an hour after the administration of the glucose the urine contained 0·9 per cent. glucose although the blood-sugar had only reached 0·137 per cent. The highest level of blood-sugar obtained during the test was 0·182 per cent. at one hour, yet the urine at one and a half hours contained 0·6 per cent. of glucose.

FIG. 5.

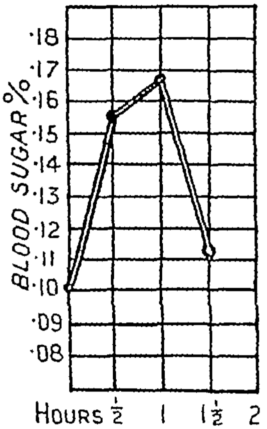

FIG. 6.

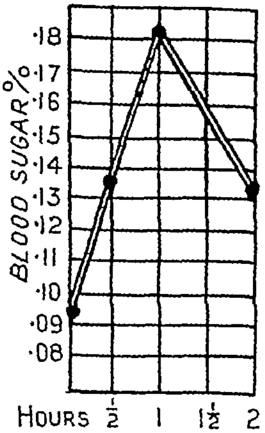

In these six it will be noted that in one case (Case 2) the morning urine contained a trace of glucose, while in the other five the morning urine was sugar-free. They would all appear, therefore, to belong to that type of renal glycosuria in which the glycosuria only appears when carbohydrates are eaten.

Cause of the Lowering of the Renal Threshold in Certain Individuals.

MacLean[13] in 1923 stated that the exact condition of the kidney which caused renal glycosuria was obscure, and recently he has expressed the opinion that the problem is still unsolved. There are, however, certain interesting observations of other investigators which are worthy of note. Hamburger and Brinkman,[14] experimenting on dogs, found that the kidney threshold for glucose could be altered by varying the amounts of calcium and potassium in the perfusing fluid, an observation which raises the question whether the lowering of therenal threshold is dependent upon abnormalities in the composition or physical characters of the blood. This interesting hypothesis has been studied by Cammidge and Howard,[15] whose observations tend to confirm this view, and they accordingly define renal glycosuria as "a condition in which there is excretion of sugar in the urine that is relatively independent of the diet and occurs in an apparently healthy person whose blood is found to contain a subnormal or normal percentage of sugar no matter when it is examined, and shows an absolute and not merely a relative reduction in the proportion of calcium." In their experiments they *found that the condition* could be controlled, for some time at least, by the daily administration of calcium and parathyroid. In Case 1 of my series no special treatment was adopted when the abnormality was discovered. Seven months later the urine, passed two hours after a mixed meal, was found to contain 2 per cent. of glucose. The patient was then advised to take each day grs. 22½ of calcium sodium lactate and gr. 1/10 of parathyroid. Three weeks later there was no reduction in the glycosuria and after five weeks the urine still contained 1·1 per cent. of glucose two hours after a test-meal. In Case 4 the administration of calcium lactate and parathyroid appeared to bring about a reduction in the amount of glucose excreted. The effect, however, was only temporary, as the glycosuria increased when the drugs were discontinued.

Possible Relationship to Disturbances of the Vegetative Nervous System.

The possible relationship between renal glycosuria and disturbances of the vegetative nervous system has been studied experimentally by several Continental workers, who have approached the subject by investigating the nature of phloridzin glycosuria. It is well known that the administration of phloridzin (a glucoside), orally or by injection, results in the excretion of glucose by the kidneys. The glycosuria thus produced is at least considerable and may be enormous. The interesting point is that it is associated with a hypoglycæmia, so that the glucose is excreted with a lowered renal threshold. In that respect it is analogous to ordinary renal glycosuria. But the full explanation of the action of phloridzin is as yet unknown, since the glycosuria produced by it continues on a carbohydrate-free diet and when the liver is empty of glycogen. One view is that the kidney simply splits off and excretes sugar from the glucoside phloridzin, which re-combines with the blood-sugar, thus forming a cycle. On the other hand, it is held by some authorities that phloridzin acts by antagonizing the influence of insulin.

Zuntz[16] demonstrated many years ago that the injection of phloridzin into the renal artery of a dog resulted in the immediate elimination of sugar from the injected kidney, while the other kidney did not excrete sugar until a definite interval had elapsed, and then only in much smaller quantity. From this he concluded that phloridzin glycosuria was of purely renal origin. Later investigators, however, have raised the question of whether phloridzin acts directly on the renal cells or through the medium of the nervous system. It now appears to be definitely established, from the experiments of a great number of observers, that individuals with an increased irritability of the vegetative nervous system show an increased sensitiveness to phloridzin. Caro has demonstrated this in Graves's disease, and Grote[17] likewise has pointed out that individuals suffering from abnormalities of the vegetative nervous system, and above all from so-called sympatheticotonia, show an increased sensitiveness to phloridzin. Dünner and Mecklinberg[18] have also demonstrated that the parasympathetic exercises an influence on phloridzin glycosuria. They show that the parasympathetic depressors, calcium and atropine, have a restraining influence on phloridzin glycosuria, while the parasympathetic stimulators, potassium and pilocarpine, have the opposite effect. Goldberg[19] has studied the influence of sympathetic and parasympathetic depressors on phloridzin glycosuria and finds that the subcutaneous injection of ergotamine (a sympathetic depressor) or of atropine (a parasympathetic depressor) controls the glycosuria following phloridzin administration. When both drugs are injected together the controlling influence is more marked. Goldberg concludes, as a result of these experiments, that phloridzin glycosuria depends upon vagal and sympathetic stimulation, and that, since phloridzin glycosuria is a representative of the renal glycosurias, the dependence of ordinary renal glycosuria on *similar* disturbances of the vegetative nervous system is established.

The hypothesis thus formulated is interesting and attractive and may be the probable explanation of a certain number of cases. Four of my patients sought advice on account of nervous symptoms which might reasonably be attributed to disturbances of the vegetative nervous system. If increased irritability of the vegetative nervous system can influence the level of the renal threshold for glucose we may find herein an explanation of the view that renal glycosurics have a deficiency of blood calcium. Chiari and Fröhlich[20] have shown that the excitability of the vegetative nervous system is markedly augmented by diminishing the calcium content of the body. It is probable, therefore, that the therapeutic administration of calcium to a renal glycosuric may produce a beneficial effect, not merely by altering the chemical and physical characters of the blood, but by diminishing the excitability of the vegetative nervous system.

In the present state of our knowledge it is not possible to state definitely what is the actual cause of the lowering of the renal threshold. There may be more than one cause, but it will be readily admitted that the hypothesis of disturbances of the vegetative nervous system marks a distinct advance in the study of a difficult problem.

Symptoms due to or Associated with Renal Glycosuria.

Cammidge and Howard have found that the subjects of renal glycosuria are easily tired and are incapable of prolonged exertion, probably owing to the low proportion of circulating sugar. Other writers describe various symptoms such as nervousness and debility. Four of my patients sought advice on account of definite symptoms of ill-health, symptoms mainly of the nature of functional disturbances of the nervous system. On the other hand, it is well known that renal glycosuria is frequently discovered in individuals who are apparently in excellent health.

Generally speaking the condition is regarded as permanent and cases have been recorded in which the glycosuria has persisted for many years with no apparent effect on the general health. In Case 3 of my series the patient was debilitated and suffered from various nervous symptoms. After a prolonged holiday the general health improved greatly, the nervous symptoms disappeared, and it was then found that a meal containing a good proportion of carbohydrate failed to produce glycosuria. In Case 6 also, in which the kidney leak-point for glucose was found to be below 0·138 per cent. in November, 1924, the blood-sugar curve suggested that the patient might be a potential diabetic. Recently, however, his family doctor reported to me that the patient was in good health and that a meal containing bread and sugar had failed to produce glycosuria. It is possible, therefore, as has been suggested by others, that there may be cases of renal glycosuria which are of a temporary nature.

Renal Glycosuria and True Diabetes.

Some writers sound a warning note regarding these cases, and suggest that they may develop true diabetes mellitus. It is not clear on what grounds this assumption is made. Renal glycosurics are probably just as likely to develop true diabetes as normal people are, but there is no evidence that they are more liable. A few cases of diabetes mellitus have been recorded in which the renal threshold was low. Shapland[21] reports one case in which the diabetes was complicated by gall-stones. Cholecystectomy produced a remarkable improvement in the diabetic condition, but had no apparent effect on the level of the renal threshold. Voigt[22] reports one case in which a fractional gastric analysis revealed a total absence of free hydrochloric acid. In his patient, the administration of dilute hydrochloric acid with meals, begun after three weeks of active anti-diabetic treatment, had no effect on the glycosuria. Lawrence,[23] in a recent paper in which he describes eight cases of diabetes mellitus with renal leak-points lying between 0·08 and 0·15 per cent., expresses the view that "there seems no reason to think that the combination of diabetes mellitus with a lowered renal threshold is not a mere coincidence." So far, then, as our present knowledge goes, there is no known relationship between renal glycosuria and diabetes mellitus. Renal glycosuria has been known to persist for many years without any apparent deterioration in health. Whether the condition is liable to variations or fluctuations, or can be in any way influenced by disturbances in the general health, are questions which can only be answered by the repeated examination of a large number of cases over a prolonged period.

SELECTIVE ACTION OF X RAYS ON THE BLOOD CELLS OF THE CAT.

BY SAMSON WRIGHT, M.D., M.R.C.P. LOND.,
AND
H. A. BULMAN, M.R.C.S. ENG., D.P.H. LOND.

(From the Barnato-Joel and Physiological Laboratories, Middlesex Hospital.)

THE changes in the cells of the blood which follow exposure to heavy doses of penetrating X rays have been studied in the cat. The entire body of the animal was irradiated at 57 cm. distance for varying periods, the spark gap being 10 cm. between spheres 5 cm. in diameter, 1 mm. of aluminium being the filter. In our experience if the duration of the irradiation is 75 minutes or over, death invariably results within 5 to 12 days; with exposures of 60 minutes a proportion of the animals survive; if the period is less than 60 minutes practically all the animals survive. In the experience of this laboratory, it takes 150 minutes' exposure to X rays of this type to kill, in vitro, the cells of Jensen's rat sarcoma (i.e., this dose equals 1 rad.).

The White Cell Count.

White counts made on a series of over 30 animals brought into the laboratory showed a wide range of variation, from 6000 to 35,000 per c.mm.; the usual range was from 9000 to 20,000. Considerable day to day fluctuations may occur in the same animal (see Figs. 1 and 2); large variations occur during the course of each day, commonly less than 5000, but sometimes as much as 9000. The differential count usually shows that the polymorph cells exceed 60 per cent., but sometimes the lymphocytes may preponderate.

Effects of Irradiation.—(1) The total white count may show a transient increase during the period of irradiation, but the figures obtained may be within the normal range of variation for the animal. The count then falls, as a rule steadily, sometimes with a slight transient recovery. On the third to the fifth day the white cells may have completely disappeared from the circulating blood or may be reduced to a few hundreds per c.mm. Following exposures of 75 or 90 minutes' duration this intense leucopenia persists till death, which occurs 3 to 9 days later (Fig. 1). In animals which survive a 60 minutes' exposure, some recovery in the white count occurs on about the eighth or ninth day and this continues slowly with irregular fluctuations. With doses of 30 minutes, the total white count does not usually fall below 1000 per c.mm. and signs of recovery are shown early (Fig. 2).

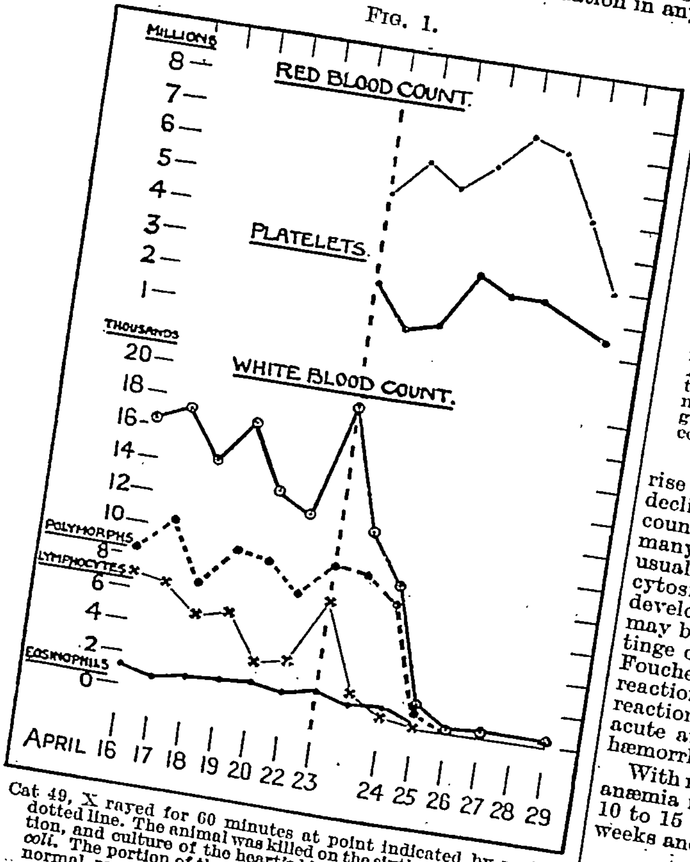
(2) The lymphocytes decrease from the onset of the irradiation; the fall continues as a rule steadily, occasionally with a slight temporary recovery. On the second or third day the lymphocytes have practically completely disappeared from the blood, even with doses of 30 minutes (Figs. 1 and 2).

(3) The polymorphonuclear leucocytes may show a transient initial increase during the irradiation. The initial changes in the total white count depend on the extent to which this inconstant increase in the polymorphs outweighs the regular decrease in the lymphocytes. The polymorphs then decrease, but more gradually than the lymphocytes; on the third to the fifth day the polymorphs may be reduced to a few hundreds or less and constitute 95 per cent. or over of the total count. With doses of 30 minutes the polymorph count does not fall below 1000 per c.mm., and tends to recover more rapidly than the lymphocytes (Fig. 2).

The Red Cell Count.

The range of variation noted in the series of animals studied was 5 to 13 million per c.mm., the usual range being 7 to 9 million. The range of fluctuation in any individual animal is commonly 1 million, and may be as high as 3 million.

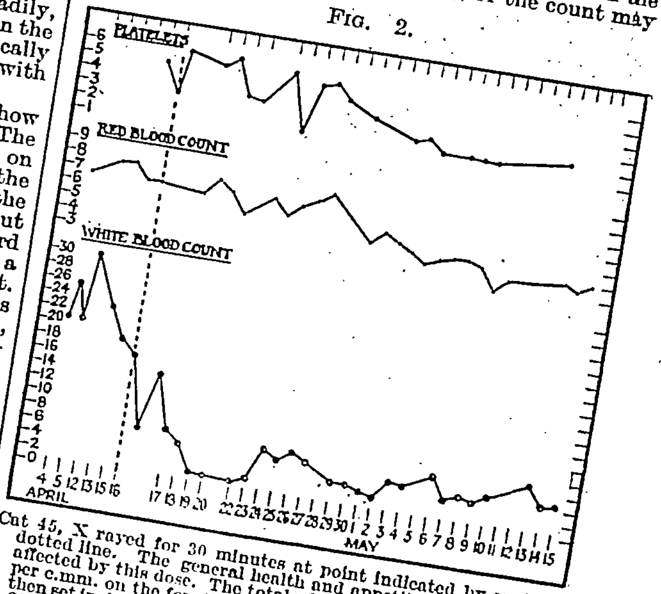
FIG. 1.



Cat 49, X rayed for 60 minutes at point indicated by vertical dotted line. The animal was killed on the sixth day after irradiation, and culture of the heart's blood showed infection with *B. coli.* The portion of the chart to the left of the arrow shows the normal range of fluctuation of the white count. The red count shows an initial increase and a terminal acute decrease, the final figure being 3 million per c.mm. The platelets show irregular fluctuations and still numbered 1·5 million when the animal was killed. There is a progressive decrease in the total white count, which fell to 200 per c.mm. on the third day after irradiation and remained at about this level to the end. The lymphocytes (normal range 3200 to 7200 per c.mm.) fell to 250 per c.mm. 24 hours after irradiation; the polymorph and eosiniphil counts decreased more slowly.

Effects of Irradiation.—The immediate effects are variable. There may be little change apart from the expected daily fluctuations (Fig. 2), or the count may rise for some days (Fig. 1), or show a steady mild decline (not illustrated). An increase in the total count is frequently associated with the appearance of many microcytes in the circulation. The red cells usually show crenation, poikilocytosis, and anisocytosis. With fatal doses a marked anæmia usually develops several days before death (Fig. 1). That this may be due to hæmolysis is suggested by the greenish tinge of the plasma which frequently gives a positive Fouchet reaction and a positive indirect van den Bergh reaction for bilirubin. The direct van den Bergh reaction in these cases was always negative. The acute anæmia may, however, result from widespread hæmorrhages.

FIG. 2.



Cat 45, X rayed for 30 minutes at point indicated by vertical dotted line. The general health and appetite were not much affected by this dose. The total white count fell to about 1000 per c.mm. on the fourth day after irradiation; slight recovery then set in, interrupted by temporary remissions. On the thirty-fifth day (not shown in chart) the count had risen to 7600 per c.mm. There was a rapid initial decrease in the lymphocytes and a more gradual decline in the polymorphs. During the recovery period the polymorph count exceeded the lymphocyte count. The red count showed irregular fluctuations (between 5·2 and 7·8 million for the first 12 days after irradiation.) From the fourteenth day the count steadily declined, the lowest value reached being 2·7 million on the twenty-second day. Slow recovery then set in; on the thirty-fifth day (not shown in chart) the count had risen again to 5·1 million, and on the 100th day it was 8 million. The platelet count before irradiation was between 3 and 5 million per c.mm. (citrate method). Observations made by the direct method for two weeks previously gave similar results (not charted). After irradiation the platelet count showed irregular fluctuations for 12 days and then sank steadily, the lowest value noted being 0·55 million per c.mm. on the twenty-second day; gradual recovery then commenced. On the 100th day the count had been restored to 3·5 million.

With non-fatal cases (Fig. 2) the development of the anæmia is more gradual, but is usually definite after 10 to 15 days. The count remains low for about two weeks and then recovery slowly sets in.

Platelets.

The range of normal variation noted in the small series studied is from 0·75 million to over 5 million. The latter figure is, of course, very much higher than that noted in man or the rabbit, but the counts have been made by two methods and repeated daily for many days so that we feel that they are substantially correct.

Effects of Irradiation.—(1) In animals that succumb the platelets have *not* shown any marked decrease before death. Thus cat 49 was killed on the seventh day when it was very ill; blood culture was positive showing *Bacillus coli communis*, but the platelet count on that day was about 1·5 million (Fig. 1). Cat 53 died on the tenth day with a platelet count of 0·75 million (see protocol); post-mortem examination showed pus in the pleura and multiple abscesses of the lungs. This is contrary to the experiences of Cramer, Drew, and Mottram[1] with the rat, who found a marked decrease in the platelet count following gamma-radiation in animals that died of intercurrent infection.

(2) In animals that survive, the platelet count generally follows the same course as the red count. For the first 12 days irregular fluctuations occur; a definite decline is then noted (Fig. 2), which continues for a number of days. The count remains at a comparatively low level for some weeks and then recovery sets in.

PROTOCOL.—*Cat 53.*

Day in May.	R.B.C. in millions per c.mm.	W.B.C. per c.mm.	Platelets in millions per c.mm.	Plasma chloride.*	Remarks.
7th.	7·4	14,400	1·2	0·605	Coagulation time 7·5 min. Wt. 2360 g.
8th.	7·9	12,000	1·1	0·605	—
	Irradiate whole animal for 60 minutes.				
9th.	7·0	7,000	0·95	—	Coagulation time 2·5 min.
10th.	8·1	1,200	1·2	0·625	—
13th.	7·9	200	—	0·625	—
14th.	8·0	800	0·9	0·625	—
15th.	7·5	600	0·63	0·615	Poikilocytosis and anisocytosis. Many very small red corpuscles.
16th.	10·2	0	1·1	0·625	Red cells very crenated and empty-looking. Very many minute red cells.†
17th.	6·6	0	1·3	0·625	Crenation and poikilocytosis less. Small red cells no longer present.
18th.	6·2	0	0·75	—	Animal very ill.
19th.	—	—	—	—	Dead.

* g. NaCl per 100 c.cm. † Evidence in counting chamber of fragmentation of red cells.

The white count showed the usual decline; no white cells were visible from the eighth day onwards. The rise in the red count to 10 million on the eighth day was associated with intense poikilocytosis and anisocytosis and the appearance of numerous very small erythrocytes. The platelets showed irregular fluctuations and numbered 0·75 million before death.

The plasma chlorides (as NaCl) fell from an initial value of 0·605 g. per 100 c.cm. to 0·615 g.

Post-mortem examination.—Pleural cavities contained much pus; multiple abscesses of both lungs. The endocardium and pericardium were turbid; there was a hæmorrhagic effusion into the pericardial sac. Minute hæmorrhages in cortex of kidney, in the spleen, and in the mucous membrane and musculature of the small and large intestine.

Summary.

This paper illustrates the selective action of X rays on the blood cells of the cat. The doses of irradiation employed were definitely less than the lethal dose for Jensen's rat sarcoma cells, approximately ¼ rad. or under.

The following is a summary of the more important changes observed.

(1) The lymphocytes are decreased early and markedly.

(2) The polymorphonuclear leucocytes after an inconstant initial increase, decrease more slowly and sometimes to a smaller extent.

(3) Marked changes in the red cell count occur later still: (*a*) in fatal cases, an acute anæmia develops in the final stages associated with evidence of hæmolysis or the presence of widespread hæmorrhages; (*b*) in non-fatal cases the anæmia develops very slowly and recovery is similarly gradual.

(4) The blood platelets are apparently unaffected in the cases that have ended fatally within a short time of irradiation, even when there is evidence of infection. In cases that survive the platelet count declines parallel with the fall in the red count, and then shows a gradual recovery.

These results form part of a more extensive research which will be published more fully elsewhere. We are deeply indebted to Prof. Sidney Russ for his advice and help throughout this work.

Clinical and Laboratory Notes.

THE COLORIMETRIC ESTIMATION OF VITAMIN A.

BY THOMAS MOORE, D.Sc.

(*From the Medical Research Council's Nutritional Laboratory, Cambridge.*)

THE original suggestion of Rosenheim and Drummond[1] that the well-known colour reaction of cod-liver oil with sulphuric acid was attributable to the presence of vitamin A has been approved with increasing confidence during the past eight years. More delicate reactions, notably with the antimony trichloride reagent,[2] have since been evolved, and by the use of a specially adopted form of the Lovibond tintometer[3] this reaction has been made the basis of a very convenient method of titration. The report of the Accessory Food Factors Committee published in THE LANCET[4] stated that in so far as concerns the grading of cod-liver oils the colorimetric method afforded information consistent with that derived from biological tests carried out in several independent laboratories. Drummond and Baker[5] have gone so far as to suggest that the vitamin may be assayed more accurately by colorimetric than by biological methods.

In other quarters, however, the specificity of the colour reactions has been questioned. On the one side Steudel and Peiser[6] have stated that the "vitamin" reaction is given by inactive crude cholesterol, while in the opposite direction Steudel[7] has also encountered a substance which although active in doses of 1·0 g., produced no colour reaction. These criticisms, although indicating certain difficulties which might arise in the application of the colorimetric technique, can be readily answered on theoretical grounds. For in the first instance chromogens derived from cholesterol may usually be readily distinguished from the vitamin chromogen by their inability to produce colorations when dissolved in natural oils; in the other direction very weak sources of the vitamin may produce colorations so faint as to escape observation unless the test is carried out on the unsaponifiable fraction rather than on the whole oil. Further criticism of the specificity of the reaction has been put forward by Hawk,[8] who has claimed that the chromogenic value of cod-liver oil may actually increase in samples exposed to climatic conditions calculated to cause destruction of the vitamin. Jones, Briad, Arzoomanian, and Christiansen[9] have also reached a similar conclusion, having found that in certain samples of cod-liver oil the colorimetric assay might exceed the biological assay by as much as 600 per cent.

Recently Euler and his co-workers,[10–14] who in a series of papers have claimed that vitamin A activity is not the property of a single substance, but may be possessed by several carotinoids or "polyenes," have indicated certain other objections to the general application of the colorimetric method of estimation. Different "polyenes" have been found to give colour reactions with varying intensity and shade, and no correlation has been found between the intensities of the colorations produced and the activity of the various polyenes. Certain polyenes—xanthophyll, lycopin, α crocetin, bixin and capsanthin—have, in fact, been found to produce colorations, although biologically inactive. Colorimetric data can therefore only be used as a basis of comparison when they are given by the same "polyene," or by a mixture of "polyenes" in constant proportions.

Preliminary experiments by the writer in confirmation of the claim that recrystallised carotin may possess intense vitamin A activity have already been mentioned in THE LANCET.[17] In view of the work of Duliere, Morton, and Drummond,[18] who have found after very thorough purification the pigment (M.P. 184·0°) becomes much less active, the main question of a possible relation of vitamin A to carotin must for the time being present a very open aspect. Nevertheless, the chromogenic properties of such samples of carotin (M.P. 174°) as have been found in my experiments to be consistently active, and also of the colourless inactive products which may be derived from them by mild oxidation, must be of immediate practical interest in illustrating certain difficulties which stand in the path of a universal application of the colorimetric technique.

It will be recalled that the well-known reaction of cod-liver oil with antimony trichloride is characterised by an absorption band at about 610 μμ, and until the discovery of the activity of carotin samples it seemed probable that the danger of the simulation of the test by casual inactive bodies could be ruled out by a spectroscopic confirmation of the position of the absorption bands. With highly active samples of carotin, however, the shade of colour produced is noticeably duller and more green, and is characterised by the appearance of an absorption band at 590 μμ. Any trace of the 610 μμ band, if present, is too weak to be detected, although judging by the biological activity well marked adsorption at this position would be expected. Vitamin A activity cannot therefore be restricted to materials producing adsorption at a specific position. Is the production of a blue coloration of any shade a sign of vitamin A activity?

In addition to the findings of Euler, experiments by the writer on the oxidation of carotin prove that this is not the case. When carotin in chloroform solution was treated in the cold with benzoyl peroxide[19] an almost complete bleaching was effected, which was accompanied by disappearance of physiological activity. Nevertheless it was found that the chromogenic value remained unaltered, and in common with vitamin A a transient blue coloration was still given even after dissolving the reaction products in arachis oil. In this case, therefore, a colorimetric assay of vitamin activity by the tintometer method would have furnished a completely deceptive result. Subsequent spectroscopic examination disclosed that the absorption band attributable to the original carotin was no longer in evidence. Selective absorption was much less clearly defined but appeared to be mainly at about 640 μμ.

The above results lend force to the suggestion of the Accessory Food Factors Committee that before a conclusion can be drawn as to the general validity of the colorimetric method of assay, tests should be made on substances other than cod-liver oil which contain vitamin A, such as butter, palm oil, cereal oils, &c. While the colour reactions of cod-liver oils, confirmed by rigid spectroscopic tests, probably provide a reliable means of estimation, the colour reactions of vegetable extracts and of some less familiar animal sources remain an almost unexplored field. Who would care to predict on purely colorimetric data whether cayenne pepper or an extract of boiled lobster shells (both rich in carotinoids) would prove effective as a source of vitamin A?

For the present it seems safe to assume that materials which give no blue coloration with antimony trichloride, even after the removal of saponifiable matter, must be devoid of vitamin A activity. Materials of liver oil origin giving colour reactions characterised by absorption at 610 μμ may be considered active. But, on the other hand, materials which give colour reactions characterised by absorption at other positions may be either active or inactive, or mixtures of inactive and active chromogens, and the biological technique still remains the only satisfactory method of assay.

AN UNUSUAL CASE OF URINARY FISTULA.

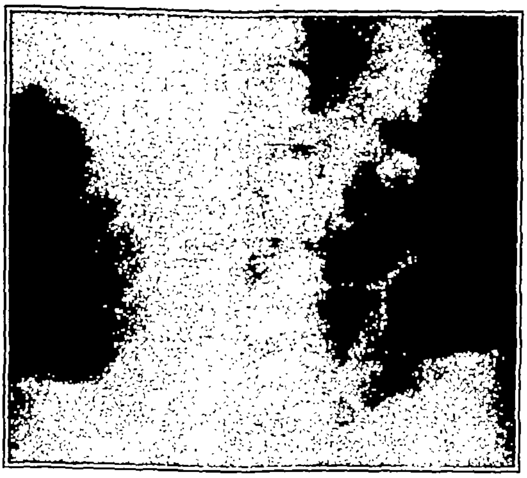
BY ALFRED C. TURNER, M.B. BELF.,

HON. SURGEON, AMERICAN HOSPITAL, TEHERAN, PERSIA.

MODERN methods of diagnosis are so reliable that the end-results of neglect are rarely seen, and therefore the following case is interesting.

In February, 1929, a tribesman, aged 36, was referred to me on account of a discharging sinus in the upper part of his left thigh. He gave a history of an attack of pain in the left iliac fossa four years previously; this had occurred every spring. Nine months earlier a swelling had appeared in the upper part of the thigh, and this had been incised by his

FIG. 1.

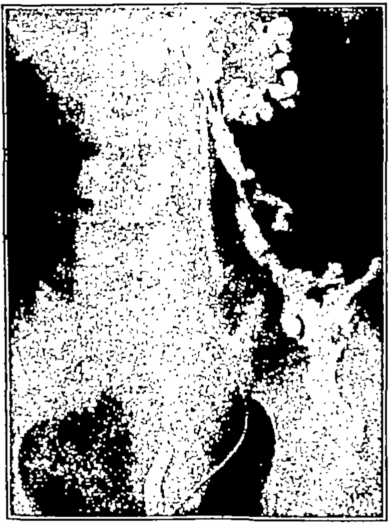


Calculi in the left kidney.

doctor and a discharging sinus had resulted. Periodically he had noticed a thick deposit in his urine, but no blood was ever present.

The discharging sinus was situated in Scarpa's triangle, immediately below the centre of Poupart's ligament, and had an orifice large enough to admit a No. 10 catheter. A probe passed without meeting any obstruction, running upwards and backwards for a distance of 6 inches. The vertebral column and hip-joint appeared normal. In the region of the left kidney, although the organ was not tender, there was a slight fullness which drew attention to it. The urine contained large quantities of pus. X ray and cystoscopic examinations were made, and the accompanying figures illustrate the condition. Fig. 1 shows the presence of renal calculi in the left kidney. Fig. 2 shows a ureteric catheter in the left ureter, arrested at the brim of the pelvis. An opaque injection has been made into the fistula and, having reached the kidney, is descending the ureter to a point a short distance proximal to the tip of the catheter, but in a more medial plane. A further radiogram showed a later condition in which the opaque emulsion, having traversed the "S" shaped course taken by the ureter was running down the ureter alongside the catheter.

FIG. 2.



Opaque emulsion in the fistula. Catheter in the left ureter.

The left kidney was explored by the usual approach. It was found fibrosed, half the normal size, and densely adherent to the surrounding structures. Numerous calculi could be felt. Owing to the adhesions to peritoneum and viscera, a nephrectomy was impossible. As decapsulation also proved unsuccessful, the kidney was split from pole to pole, and six calculi removed. A thick fibrous cord was felt joining the pelvis of the kidney at the junction of the inferior calyx, and on removal of a calculus from this calyx a large quantity of pus welled up. No normal tissue could be demonstrated in the kidney, which was left open and drained. Two months after operation the sinus had closed, the nephrotomy wound healed, and when the patient was discharged he had no symptoms and had gained weight.

My explanation of the sequence of events which led to the condition found at operation is that, owing to delayed diagnosis, the chronic inflammation caused such dense adhesions that an abscess formed within the psoas sheath and tracked down to Scarpa's triangle.

BRITISH MEDICAL ASSOCIATION.

ANNUAL MEETING IN MANCHESTER.

PROCEEDINGS OF THE REPRESENTATIVE BODY.

(Concluded from p. 197.)

Heroin: An "Oppressive Restriction."

THE Dangerous Drugs Acts, and especially the new regulations about heroin, produced a crop of protesting resolutions, and Dr. J. W. BONE took the opportunity to explain how the situation had arisen. The Act of 1920, he said, under which the profession had worked quite happily, required that practitioners should keep a record when prescribing drugs containing more than 0·1 per cent. of morphine or heroin, or 0·2 per cent. of cocaine or opium. In 1925 Great Britain pledged herself at Geneva to apply the Dangerous Drugs regulations to all preparations of heroin, of whatever strength, and this provision of the 1925 Act came into force on Jan. 1st of the present year. The Association had actively objected to it in 1925 and was still in correspondence with the Home Office. Sir Malcolm Delevingne's principal argument now seemed to be that nothing could be done in face of the international agreement, but in point of fact the Convention stipulated that the requirement to enter the quantities distributed need not necessarily apply to supplies dispensed by medical practitioners or to sales by duly authorised chemists. Unfortunately, the Act of 1925 which applied the Convention to this country contained no such proviso and said definitely that any strength of heroin must be recorded. Dr. Bone had always thought this an oppressive and unnecessary restriction on medical practice and at last he was finding wide support for his views. He thought the meeting might well suggest that legislation to amend the Act in this sense should be encouraged. It was commonly said, he added, that Great Britain was the only country which had honourably tried to carry out the terms of the Convention and that the United States had taken no steps to ratify it. America was, however, in a fair way towards cutting heroin out of the pharmacopœia of every doctor; and with good reason, for in the States heroin addiction was undoubtedly a serious problem and justified measures which he saw no reason to enforce in this country.

Dr. R. M. MANWARING-WHITE spoke of the great value of heroin in such conditions as dry irritable cough, and suggested that its use might be diminishing under the present exacting restrictions. He understood that there were practically no heroin addicts in this country.

Dr. JOHN STEVENS held that there was no reason for extending the restrictions to this valuable drug for which there was no really adequate substitute—and proposed for Edinburgh and Leith a motion which strongly supported the Council "in its effort to obtain amendment of Section 8 of the 1925 Act," and recommended that "heroin and its salts should come under the same conditions as morphine and its salts." This motion was passed by the Representative Body, with the following addition made at the instance of Dr. F. TEMPLE GREY:—

> Also that the Council should on all possible occasions urge the Government not to enter into international conventions involving medical questions until the opinion of the medical profession has been ascertained.

Dangerous Drugs and Record-keeping.

Dr. STEVENS got little support for his complaint that it is impossible for a practitioner to have his stock of dangerous drugs under lock and key and at the same time have them available for inspection in his absence, but a discussion arose on the third proposition which he brought forward for his Division.

The Regulations say that no record need be kept when a drug or preparation is *administered* by, or under the direct supervision and in the presence of, a doctor. Dr. Stevens suggested that a similar exception might be made when it was administered "under his authority given to a nurse or other responsible person."—Mr. DAVID LEES supported this proposal on the ground that it provided an alternative to the present system under which a medical man might prescribe 50 or 100 tablets and send them to a nursing home where they could be used ad lib. by the patient.—Dr. F. RADCLIFFE said he understood that if nurses in a home administered doses of morphia and entered these doses in a book, kept at the home, this would cover what the doctor had ordered by lots of 50 or 100.—Dr. BONE, in reply, described the practice mentioned by Mr. Lees as quite irregular, and made it clear that a record must certainly be kept if a dose is given in the absence of a doctor. In the case of a hospital or nursing home a book must be provided for the purpose by the institution; where, on the other hand, the drug is given by a nurse to a patient in a private house, the practitioner who has supplied it must enter the doses on his own register.

The amendment proposing an alteration in this rule was lost by a large majority.

Relation of the Private Practitioner to the Public Health Services.

Last year the Representative Body viewed with concern "the insidious inroads continually being made on private medical practice under the auspices of the State, voluntary bodies, and others," and recorded its opinion that "the increasing tendency to transfer the treatment of many diseases and conditions to whole-time medical officers" is detrimental to the public health. Dr. Alfred Cox, the Medical Secretary, has since reported personal investigations into the working of maternity and child welfare centres and school clinics, and the Council has prepared an elaborate report whose conclusions and recommendations were presented to the meeting by Dr. BONE.

After stating that the main sphere of the private practitioner is the giving of medical advice and treatment to individuals, whereas the main sphere of the public health officer is the promotion of healthy conditions for the community, the Council goes on to point out that there is no definite line of demarcation between these spheres and that in both there is need and opportunity for clinical and preventive work. So far as possible the private practitioner and the medical officer should associate themselves, and be interested in, each other's work; nevertheless "the general direction of services established by or under the auspices of the local authority should be entirely within the province of the public health medical officer; and equally no clinical work should be undertaken by public health medical officers which can, with due regard to administration, be done as well by private practitioners." The profession, says the Council, recognises the propriety of central departments and local authorities making provision for medical advice and treatment, but public centres and clinics should not be developed in such a way as to militate against or interfere with suitable developments of a contributory National Health Insurance scheme for the appropriate sections of the population.

> "The work of such clinics should therefore be primarily directed to education in the general rules of health and of hygiene; medical or surgical advice or treatment for the individual should be confined (*a*) to such treatment as can be actually given therein, and should not include any treatment that makes domiciliary attendance advisable or involves a stay of more than 48 hours at any clinic where beds are provided; and (*b*) to those patients who are unable for some reason to obtain treatment from a private doctor and those who, as a result of supervisory medical work undertaken by the local authority, are discovered to be ailing, and for whose ailments treatment would not be sought unless it were provided by the local authority."

The question of the existence of a family doctor, or of the possibility of securing one, should be raised, the Council maintains, in respect of every case attending a clinic, and such officers as health visitors and midwives should be actively discouraged from sending direct to a clinic any cases which can be dealt with privately. The question how far private practitioners can undertake the work of the clinics should be seriously considered in each locality in conference with local practitioners, and wherever practicable "all medical advice and treatment at local clinics should be given on a part-time basis by private practitioners, whether it is within the sphere of general practice or whether it is of a specialist character." Those who accept such service must, it is emphasised, be genuinely interested in the work they undertake to do and must look on it as the first call on their time.

Dr. EUSTACE HILL, supporting these recommendations, cited instances in which maternity and child welfare work was very well done by private practitioners on a part-time basis, but pointed out that some medical men did not like sending their patients to clinics run by other doctors practising in the same district. The work of a welfare centre was seriously interrupted if a practitioner failed to attend because he was looking after his own affairs, and it could not be conducted on this basis. Despite undoubted administrative difficulties Dr. Hill felt that part-time work had many advantages.—Dr. E. R. FOTHERGILL spoke of the revolutionary changes in medical work since the beginning of the century, and said that the Council was hoping to present to the next Representative Meeting an ideal scheme for medical service in this country, showing the lines further changes ought to take.

A number of details arising out of the report were referred to the Council for consideration, but the conclusions and recommendations outlined above were accepted without much discussion.

Dr. C. FORBES, for Aberdeen, proposed "That the functions of the health visitor and district nurse could with advantage be fulfilled by one and the same person or public nurse; and that this public nurse, for purposes of domiciliary health education and propaganda, should be under the immediate direction of the family doctor, where such exists." This plan, he said, had been successfully tried in Aberdeenshire. But it did not commend itself to the Representative Body, and Dr. EUSTACE HILL described it as an encroachment on the sphere of preventive medicine which would certainly not be acceptable to local authorities in England.

Reform of the Poor-law.

Dr. BRACKENBURY reminded the meeting that under the new Local Government Act the councils of counties and county boroughs were now preparing schemes for carrying out the functions which would be transferred to them next year. If they liked to do so these councils could go a long away towards getting unified public health services. On the other hand, they need not. The Association was anxious to get them to break up the poor-law so far as they were able and use their other legislative powers instead. It also felt that the work would not be done as efficiently as possible unless medical men and ex-guardians were coöpted as members of the new poor-law committtees. The Council of the B.M.A. was therefore scrutinising the schemes as they appeared. There was a very unfortunate circumstance, however, which made one section of the Act almost a farce. It was laid down that the schemes had to be submitted by Sept. 27th, and as most of the councils did not meet in August or September the result was that many had already been published, whilst many others would appear shortly. The schemes were open to criticism for only four weeks after publication, and the effect of submitting them at this time of year was to prevent their consideration by local district councils or by central bodies such as the B.M.A. This had certainly not been the intention of Parliament, and he appealed to local authorities to defer the actual submission of their schemes until the last possible day.

Dr. Brackenbury also referred to Section 13 of the Act, which says that before making any additional hospital provision, or any different use of transferred hospitals, local authorities must consult any body which they regard as representing the voluntary hospitals of their area—including both the medical staffs and the governing bodies. It was highly important that in every area there should be such a body and the Council earnestly asked members of the profession to take immediate steps to promote the formation of these consultative committees. If there were cottage hospitals in the district they too should be represented.

Representation of Profession on Local Authorities.

Speaking on another section of the Council's report Dr. Brackenbury pointed out that more and more members of the medical profession were being drawn into contractual relation with the work of the local authorities. This meant that more and more were being legally deprived of the right to take part in public health work as members of those authorities. The Local Government Act would greatly swell the numbers of those whose medical experience could not be placed at the disposal of the community, and the Ministry of Health realised that this was not in the public interest. It was interesting to note that teachers were not debarred from belonging to education authorities, and were indeed obliged to send representatives.—In the course of a brief discussion on this topic a representative said that he had two partners, one of whom did part-time work at a public clinic. Because of this appointment all three members of the firm were prevented from taking any part in the government of their town.

Representation of Profession in Parliament.

So much non-controversial talk proved a little enervating, and everyone brightened up noticeably when asked to destroy the Association's Parliamentary Elections Fund. The Chairman and the meeting amiably accepted an assurance from representatives of the press that they would observe their usual discretion in suppressing names and details, after which Dr. E. K. Le Fleming entered on an account of the Fund's recent history. It had proved impossible he said, to support any Labour candidate at the general election principally because the Labour Party still held by nationalisation or municipalisation of all hospitals and the ultimate establishment of a whole-time salaried State medical service. As stated in the published report of the Council, approval and support had been given to the candidature of two members of each of the other parties—namely, Dr. J. H. Morris-Jones (Lib.), Dr. A. Vernon Davies (Cons.), Dr. J. Vincent Shaw (Lib.), and Dr. L. Haden Guest (Cons.), all of whom expressed themselves as in favour of the Association's policy. The two former had been elected. The Fund, said Dr. Le Fleming, had not been too well supported, but after much thought he had come to the conclusion that it served a useful purpose. It was valuable to have in the House medical men who could accurately represent the views of the profession as set out in the policy of the B.M.A.

Dr. Fothergill, proposing for Brighton that the Fund, having failed of its purpose, should be wound up and that the money should be used for cognate purposes, said that legislation was now done in Whitehall, not at Westminster. An M.P.'s duty was first to his party, then to his constituents, and then to his profession. Some would put conscience first; in a few instances this might be so. At any rate, the Association was already in a position to approach the central authorities at Whitehall and the local authorities elsewhere, and it could best gain its ends in this way.—Mr. Bishop Harman also wanted to kill what he described as "this untimely child," and the proposal got further support from Dr. Peter Macdonald, despite (he said) the arguments advanced in its favour.

Sir Richard Luce said he had always been opposed to the Fund and had never been ready to take anything from it. After a man's duty had been done by conscience, constituents, and party—in that order, he thought—what then was left? A Member of the House who was paid to represent some outside body—that was what it came to—was liable to the taunt that he went there to represent special interests. To be in such a position was unpleasant, especially to a professional man. Anyone familiar with medical work would be listened to in Parliament with respect and attention, but he would have nothing like the same influence if it was recognised that he was there to support the interests of his profession. Sir Richard did not believe, moreover, that the Fund had ever got a man in who would not have been elected without its help.

Dr. D. F. Todd spoke of the educative effect of having medical men in the House. They went not to represent the profession directly, but to represent the community.—Dr. S. Morton Mackenzie wanted to let the Fund go on, and so did Mr. McAdam Eccles.—Dr. Brackenbury said it had failed financially, but in a more modest form was an essential part of the machinery; Dr. Temple Grey pleaded for its abolition; Dr. Le Fleming replied in its defence; and eventually Dr. Fothergill's resolution to wind it up was put to the meeting and defeated.

A Medical Ophthalmic Service.

As there is little likelihood of any draft regulations about ophthalmic benefit being issued in the near future the Council has agreed that the National Ophthalmic Treatment Board shall put into operation a scheme for an ophthalmic service approved by the Representative Body last year.

By arrangement under this scheme, it is stated, insured persons and their dependents may have their eyes examined "by an ophthalmic medical practitioner at his private consulting room," and obtain spectacles, at an inclusive fee of 18s. Arrangements have also been made whereby non-insured persons who cannot afford the ordinary fee and whose family income does not exceed £250 a year, may take advantage of these facilities. The spectacles will be supplied by members of the Association of Dispensing Opticians, who practise no sight-testing. The scheme will be administered by a National Ophthalmic Treatment Board comprising representatives of this association and of the B.M.A.; the Minister of Health, and approved societies are also being invited to send nominees. Particulars may be had from the general secretary of the Board at 1, High-street, Marylebone, London, W. 1.

Dr. R. Wallace Henry (chairman of the Ophthalmic Committee) said he believed the scheme would be found quite workable, and Mr. Bishop Harman described it as a really valid attempt to cater for one of the great needs of civilisation. He believed it would be adopted by public authorities and other organisations to the great advantage of the public.

Vaccination.

Newcastle tabled a resolution demanding that "Government lymph should be available for all practitioners and that every general practitioner should be able to vaccinate his own patients in the same way as public vaccinators, and obtain similar remuneration from the Government." Bath wanted the meeting to pass a statement that—

> The Representative Body views with concern the spread of small-pox in this country and the difficulty of ensuring adequate vaccination of the public; that one of the reasons for this inadequacy of protection is the uncertainty of certain preparations of vaccine lymph; that sometimes these fail to produce reactions and vaccinated persons acquire small-pox, at other times the reaction is so severe that the health of the patient is seriously affected; that experience shows that these objections do not apply to Government lymph, but this is not available for other than public vaccinators, and in the case of immediate contacts for medical officers of health; and that the Representative Body urges the Council to represent to the competent authorities that vaccination cannot be properly promoted unless they are prepared to provide Government lymph to private practitioners (if necessary on payment) or to give a Government guarantee of efficiency to supplies of lymph prepared by private firms.

In 1923 the Minister of Health told the Association that he understood there was no difficulty in obtaining supplies of glycerinated calf lymph from reputable firms, that the Government Lymph Establishment was established to provide lymph for the primary vaccination of infants by Government vaccinators, and that the supply of such lymph to doctors would involve a large and costly extension of the present supply for which he saw no need.

This statement, which has since been repeated several times, was criticised for Bath by Dr. R. G. GORDON. It was time, he said, that everyone woke up to the fact that the incidence of small-pox was becoming serious. The lymph obtainable from reputable firms was sometimes ineffective and sometimes drastic in its action. He would say nothing about post-vaccinal encephalitis, because our present knowledge did not justify dogmatic statements about it. It was recognised, however, that on the whole Government lymph gave relatively constant results, and at a time when small-pox and the disuse of vaccination were both increasing it was surely not too much to ask that a supply of such lymph should be available.—Dr. MIDDLETON MARTIN thought that the grave difficulties in the way of getting the public to appreciate the importance of vaccination should be combated by encouraging practitioners to use their influence in the home. He hoped that further facilities would be provided.

In the subsequent discussion a public vaccinator was quoted as saying he had never had a failure with Government lymph in 21 years—whereas lymph from a private firm might give as few as 25 per cent. of "takes"—and Dr. W. N. WEST-WATSON said he had been struck by the small proportion of successful results with the lymph he had been using recently.—Dr. B. H. PAIN said that when some years ago he proposed in the *Times* that every medical man should vaccinate his patients at the cost of the public an inspector from the Ministry informed him that this would be expensive and would involve placing practitioners under supervision. Accurate records had to be kept so that if anything went wrong the lymph could be traced to its origin.

Dr. BRACKENBURY recommended caution, if only because there were members of the Association whose livelihood depended on the private manufacture of lymph. When vaccine proved ineffective complaint should be made to the Therapeutic Substances Act Advisory Committee.—The CHAIRMAN (Dr. Hawthorne), as a member of that committee, said that there were inspectors under this Act just as under the Food and Drugs Act. Though these inspectors examined samples of lymph as part of their duties, their procedure would doubtless be hastened by specific complaints.—Dr. C. E. S. FLEMMING maintained that if this Act controlled the preparation of lymph, then its control was inadequate. A number of people in his district had been made seriously ill by vaccination, and this had naturally affected public opinion adversely.

Dr. J. B. MILLER said that the general practitioner, who had to take the responsibility of advocating vaccination, ought to be able to feel confident in the lymph used for the purpose. Dr. Miller did not regard official supervision as a hardship; but Dr. E. LEWYS-LLOYD (Chairman of the Public Health Committee) remarked that if anyone was under the impression that the record-keeping and inspection of public vaccinators were nominal, he was making a mistake. In Dr. Lewys-Lloyd's opinion the Therapeutic Substances Act did give a guarantee, and if any sample of lymph was inefficient the machinery of this Act should be set in motion.

Ultimately the proposed resolutions were referred to the Council for consideration.

A State Medical Service: Possible Unsoundness of the Young.

Bearing the arms of Kensington Mr. E. B. TURNER entered the lists with a motion condemning the project of a whole-time salaried State medical service and calling on the Association to educate and organise its members to resist any legislative attempt to set one up. The proposal would either have to be fought or allowed to go by default; and he was all for fighting. If the profession felt about it as he did, then steps should be taken to form opinion. There was a large body of younger men whose outlook was largely bounded by contract practice, and who would easily be lured into a State medical service. "Si vis pacem, para bellum," said Mr. Turner—apparently unaware that the sentiment is out of fashion.

Dr. BRACKENBURY was almost scornful. The motion had an air of panic. If one thing was certain it was that the whole medical profession was fully decided that it would not work a whole-time medical service.—And did Dr. Brackenbury remember, asked Mr. TURNER, how sound and solid the profession had been about national insurance? How 27,000 practitioners had said they would not go on the panel till the B.M.A. took away its embargo, and how they flocked to do so before that embargo was removed? Would it not have been better then not to have passed quite so many unanimous resolutions at crowded meetings, but rather to have considered and discussed the views of the silent minority?

Dr. H. S. BEADLES did not believe the profession was "solid" at all. He thought many young men would willingly join a whole-time service, though they would not be wise to do so.—The same view was taken by other representatives, one of whom spoke of an "enormous number" of men who wanted such a service.—Mr. BISHOP HARMAN said this was absurd; 99 men out of 100 had spunk enough not to prefer whole-time salaried work to the adventure of practice.—Dr. C. E. S. FLEMMING suggested that the best way to meet this talk about a State medical service was to formulate a comprehensive scheme in its place, as the Council hoped to be able to do next year.—Finally a member who rashly compared the advantages of private practice and public work was eliminated by Dr. BRACKENBURY, who said that such comparison had nothing to do with the case. What the Association had always set its face against was not the public health service, but rather the stereotyping of ordinary family practice into the form of a State medical service. In favour of this, he repeated, there was *no* considerable body of medical opinion.

Not much more was said on this subject. Rejecting Mr. TURNER's motion for mobilisation, the meeting contented itself with reaffirming its former convictions on the subject of a State medical service.

Need of Superannuation Schemes for Medical Officers.

Arising out of the case of the late tuberculosis officer for Gateshead, who is believed to have contracted encephalitis lethargica from a patient in the course of his duty and on losing office received no compensation in spite of steady pressure on the local authority concerned, Dr. R. FORBES for Gateshead proposed:—

That . . . it be an instruction to the Council: (*a*) to take such action as it deems necessary to urge local authorities to adopt superannuation schemes under which the medical officers and their staffs would benefit. (*b*) To make strong representation to all local authorities that where a medical officer is disabled permanently or with fatal results, through contact with infectious diseases, and where his disability is directly traceable to his work in this respect the dependents of the practitioner should be suitably compensated for the loss involved.

Describing the case as one of great hardship, Dr. Forbes said that a medical officer who was required to stand between the community and infectious disease ran a rather special risk, and it was not too much to ask that the community should compensate him or his dependents.—The motion was carried.

Remuneration of Poor-law Medical Officers.

Attention was drawn by the North of England Branch to the deplorable conditions of service under which poor-law medical officers are at present working in areas where unemployment is rife.—Dr. R. FORBES said that the question was national rather than local, but Dr. BRACKENBURY replied that the Council, while fully aware of the misfortunes of these officers on Tyneside must also take into account the fact that in many parts of England medical men would be sorry to have the terms of their service reviewed. The following motion by Gateshead was approved:—

> That the Representative Body, recognising that poor-law medical practitioners will shortly become the servants of a new authority, considers that the time is now opportune to explore the status and remuneration of these officers, and instructs the Council to examine the whole matter and take such steps as are necessary to secure equitable terms of service and adequate remuneration for the work involved.

Other Subjects Discussed.

The meeting agreed to the two following proposals of the Council:—

> That the Representative Body reaffirms the opinion it expressed in 1924 that the General Medical Council and the profession generally have acquiesced in the custom, now of long standing, of advertising in the lay press, nursing homes, sanatoria, and hydropathic institutions, and feels that, in any policy formulated by the Association, regard must be had to this custom; and further that the R.B. takes no exception to the association of registered medical practitioners with an institution for the treatment of patients by physiotherapeutic and electrical methods, provided the following essential conditions are strictly conformed to: (*a*) That the institution is not in any way advertised to the lay public; (*b*) that the treatment of all patients is under the direct control of a registered medical practitioner who accepts full responsibility for their treatment; (*c*) that the relation between the medical officer of the institution and private practitioners conforms to the usual ethical procedure between consultant and private practitioner.
>
> That the following Clause 1 (1) of the Preservation of Infant Life Bill (as sent from the House of Lords to the House of Commons) be approved:—1.—(1) Subject as hereinafter in this subsection provided, any person who, with intent to destroy the life of a child capable of being born alive, by any wilful act causes a child to die before it has an existence independent of its mother, shall be guilty of felony, to wit, of child destruction, and shall be liable on *conviction thereof on indictment to penal servitude for life*; provided that no person shall be guilty of an offence under this section unless it is proved that the act which caused the death of the child was not done in good faith for the purpose only of preserving the life of the mother.

Dr. ELEANOR LOWRY, for Marylebone, proposed a motion (which was carried) deploring "the insufficient provision which exists for the administration of the beneficent provisions of the Mental Deficiency Acts" and assuring the Minister of Health of the support of the B.M.A. in urging the local authorities to meet the grave need for institutional care.—Dr. H. C. BRISTOWE spoke strongly of the extent of this need, and Dr. A. HAWKYARD mentioned that unfortunately attempts to get defectives into institutions were often hampered by members of the medical profession whose only object sometimes seemed to be to get their patients off. There was very little knowledge of the Acts among practitioners.

Dr. TEMPLE GREY proposed for Marylebone that "communications between doctor and patient, unless they concern fraud or crime or otherwise the public interest, ought to be privileged from disclosure in courts of law." The extreme view of the sanctity of medical privilege was, he said, not the medical but the social view. The public would demand medical privilege as soon as they realised that it was *their* secrets which were being given away.—The motion was *referred to the Council.*

On the report of the Organisation Committee Dr. MORTON MACKENZIE said that whereas there were only 1852 women medical practitioners in this country in 1922, the number in July of this year was 4259, of whom about two-thirds were members of the Association.

The Council's negotiations towards the establishment of an international medical sea code were approved. Dr. BONE said that the Board of Trade hoped to be able to make good use of the code proposed.

The General Medical Council.

It was announced that at the forthcoming election of Direct Representatives of the profession on the General Medical Council the candidature of Dr. H. B. Brackenbury and of Mr. N. Bishop Harman would be supported by the Association.

The CHAIRMAN and others referred in very warm terms to the work of Sir Jenner Verrall, who is resigning from the G.M.C. after over 18 years' membership. A resolution of deep appreciation of his services was placed on record.

THE ANNUAL GENERAL MEETING.

On July 23rd the retiring President, Sir Ewen Maclean, invested Prof. A. H. Burgess with his badge of office, after which the Chairman of Council, Dr. Brackenbury, invested Sir Ewen with the new past-president's badge. In reporting that the Representative Body had elected Dr. W. Harvey Smith, professor of ophthalmology in the Manitoba Medical College, as President for 1930–31, Prof. Burgess said that the last meeting of the Association held abroad was at Toronto in 1907, and that the next would be at Winnipeg in 1930 under Prof. Harvey Smith's presidency. The treasurer, Mr. Bishop Harman, formally presented the new symbolic staff which he has given to the Association.

At the adjourned annual general meeting later in the same day the President delivered the address which we published last week. He presented the Sir Charles Hastings clinical prize to Dr. Arthur Crook, of Norwich, the Hempson prize to Dr. A. C. T. Perkins, of Bury St. Edmunds, and the Middlemore prize to Mr. W. S. Duke-Elder.

THE RELIGIOUS SERVICE.

The Bishop of Manchester, the Lord Mayor of Manchester, the Mayor of Salford, the Chancellor and Vice-Chancellor of the Victoria University, and officials of the Association attended the service in the Cathedral on the 23rd. The Archbishop of York was the preacher. In the course of his sermon Dr. Temple suggested that the advance of science was liable to create a sense of insignificance in mankind and thereby might operate against the sense of responsibility which was one necessary part of the religious man's existence. Yet it was part of all religions that every moral choice made by human beings mattered more than the course of the stars to God who made them all. All new knowledge of the world was and had to be new knowledge of God.

SOCIAL AND OTHER FUNCTIONS.

The annual dinner of the Association was held in the Free Trade Hall on July 25th, Prof. A. H. Burgess presiding. Covers were laid for 600 guests, and more would have attended had it been possible. After the loyal toast ("The Duke of Lancaster"), Dr. W. J. Mayo proposed "The Cities of Manchester and Salford," recalling the fact that his father was a student in Manchester under John Dalton, and that the *Guardian* was quoted all over the United States as a sound, logical, honest, and fearless paper. Alderman Davy and Councillor Collins, in reply, both claimed Dalton, and made play of the administrative problems of two communities situated at each others' doors. Dr. A. T. Bazin, President of the Canadian Medical Association, invited the company to toast the sister Association, and Dr. H. B. Brackenbury, in responding, took the chance of setting out what the B.M.A. was and what it was not. The toast of "Our Guests" was proposed with infinite humour by Sir StClair Thomson, and responded to in the same vein by Judge T. B. Leigh. Lord Moynihan, proposing "The President," spoke of him as an "artist" in his craft. Prof. Burgess thanked all who had contributed to a successful meeting (not excepting the "Clerk of the Weather"), and especially the local general secretaries, Dr. E. Bosdin Leech and Dr. R. G. McGowan.

Honorary degrees were conferred upon a number of distinguished visitors at a congregation of Manchester University, held in the Whitworth Hall on July 24th, the Earl of Crawford and Balcarres presiding. The degree of Doctor of Laws was conferred on Dr. C. H. Mayo, Dr. W. J. Mayo, and Lord Dawson of Penn; that of Doctor of Science on Dr. C. O. Hawthorne and Sir Ewen Maclean. In replying for the recipients, including those whom he described as the "Heavenly Twins in Surgery," Lord Dawson said that the Public Orator, Prof. S. Alexander, had referred to Rochester as the Mecca to which all were drawn. To Britons, it was, he thought, more than that; it had played no mean part in strengthening the sense of unity between the free peoples on the two sides of the Atlantic. Among the problems to be faced by medical faculties was, he said, one of real importance at the present time; that was to try to bring about closer contact between the universities and the health services, not least to secure for the officers and workers in those services academic guidance and recognition.

On July 25th the Bishop of Manchester dedicated in the Eccles Parish Church a stained glass window, given by the Mayo brothers in memory of their father, William Worrall Mayo, who was born at Eccles in May, 1819, and died at Rochester, Minn., in March, 1911. In the inscription he was described as a pioneer, physician, citizen, a man of hope, vision, and achievement.

THE ANNUAL EXHIBITION.

An exhibition of surgical instruments and appliances, drugs, foods, books and the like, held in the City Exhibition Hall, Deansgate, from July 22nd–26th, was well arranged and attended. Some account of it will appear later.

COMBINED SECTIONS OF SURGERY, PHYSIOLOGY, AND BIOCHEMISTRY.

ABDOMINAL PAIN.

Opening Addresses.

Prof. E. D. TELFORD (Manchester) being in the chair, Dr. C. H. MAYO (Rochester, U.S.A.) opened the discussion by remarking that to-day the prize-fighter was not alone in his appreciation of the importance of the solar plexus. Abdominal pain, it was now generally agreed, was not merely a question of referred pain or of viscero-sensory reflexes. The structures in the abdomen were themselves sensitive to such stimuli as pulling—to undue contraction or distension. Even the solid organs, such as the liver and ovary, had proved themselves sensitive in operations performed under local anæsthesia, and it was well known that the puncture of an artery could be exquisitely painful. The parietal peritoneum was, of course, very susceptible to stimuli because of its rich innervation from the intercostal nerves, but the visceral peritoneum was also sensitive because of the white medullated fibres described by Langley in the splanchnic nerves. Dr. Mayo dealt at some length with the types of pain met with in gastric crises, their varying incidence, location, and duration, agreeing with Ryle that a more careful analysis of pain was necessary. He admired the contributions of the physiologists, and found Adrian's "Basis of Sensation" wholly delightful and extremely illuminating. Nevertheless, he concluded, "I think I have said enough to convince you that when the character and site of an abdominal pain tells something to the surgeon it does so not because he knows much about the underlying anatomy and physiology, but because he has encountered that particular pain many times before, and he remembers what he found when he opened the abdomen."

Sir FARQUHAR BUZZARD (Oxford) spoke on a more general and philosophic plane. He reminded his hearers that pain was, to the moralist, a corrective, to the physiologist, a protective mechanism, to the clinician, it played its part in healing, but we were not primarily concerned here with the question of the usefulness or uselessness of human suffering. As regards the abdomen, he regarded the territory of the sympathetic nervous system as presenting problems fundamentally different from the ordinary reflex phenomena of skeletal muscle. It was Ross of Manchester who clearly separated somatic from visceral sensation. However great were our difficulties, we should not hide our ignorance behind a diagnosis such as psychalgia or functional pain, and he hoped for the abandonment of such loose terms as rheumatic, neuritic and neuralgic. Sir Farquhar also dealt with the problems of gastric crises, and thought we might come to a diagnosis in such cases "without the necessity of worrying the patellar tendons." He quoted Hilton, "Every pain has its distinct and pregnant significance, if we will but carefully search for it."

Discussion.

Mr. JOHN MORLEY (Manchester) dealt with the views of Sir James Mackenzie on referred pain. He described some of the experiments he had made with Dr. Twining in which it was clear that the position of deep and sharply localised tenderness varied quite materially with posture, and again how referred pain could be proved to be referred, not from the viscus, but from the parietal peritoneum—e.g., from the diaphragmatic surface along the phrenics and to the shoulder. Dealing with the work of Weiss and Davis, in which the effect of local anæsthesia on the areas of referred pain had been investigated, he had repeated their experiments and in the main confirmed their findings. Their support of the Mackenzie view which they thence argued was, however, wrong, for in cases in which the abdomen was opened under spinal anæsthesia, a swab inserted under the diaphragm on one side caused referred pain in the corresponding shoulder, which could be abolished with local novocaine. If the swab were now transferred to the other side of the diaphragm there was extreme pain in the other shoulder, proving, since the spinal paths were blocked, that the impulses were spreading from the diaphragmatic peritoneum via the phrenic nerves. He regarded the application of analogies from the cardiovascular and genito-urinary systems to the intraperitoneal organs as most unfortunate, and maintained that Mackenzie's viscero-sensory and viscero-motor reflexes were twin phantoms, whose abolition would make diagnosis simpler and more accurate.

Dr. E. P. POULTON (London) thought that a reasonable physiological interpretation could be formulated to cover the facts of abdominal pain as at present known. He showed how, in a hollow organ, we should regard tonus rings simply as points where the tension is lower than elsewhere. Describing his experiments on the œsophagus, in which various arrangements of bags can be swallowed and held at different levels and the pressures within them recorded, he pointed out that pain was associated not with contraction but with relaxation. When and where the peristalsis was held up there was extreme pain, and the most severe type of colic was associated with such a hold-up of the peristaltic waves. He indicated how useful information about pain in the chest might be got by noting its relation to swallowing. If felt *after* swallowing the source of the pain was œsophageal. Other types of pain might be stopped entirely by swallowing, or made infinitely worse as in certain dyspepsias.

Dr. A. F. HURST (New Lodge Clinic) thought it unwise to underestimate the importance of reflexes, and said that is was evident from what we knew of the gall-bladder and appendix that visceral pain was mainly due to distension. Localisation in space of the members of the body was mainly due to the impulses arising in muscles, bones, and joints, but there was no similar rigid fixation amongst the viscera. Where an organ was fixed, the localisation of pain was very accurate and informative, but not so in movable organs. In his experience the localisation of pain did not vary with the changes in position of the organ. Pain from the appendix was usually sharply and constantly localised. From the terminal ileum it was referred to the umbilicus, but from the pelvic colon it was merely felt vaguely above the umbilicus in the mid-line. Directly the distension passed from the pelvic colon to the rectum, the pain moved to the perineum, as in the normal call to defæcation. He was not convinced that referred pain in the Mackenzie sense did not exist, and thought that the better study of abdominal pain should do much to improve diagnosis.

Resumed Discussion.

After a brief interval the discussion was resumed under the chairmanship of Prof. H. S. RAPER (Manchester).

Dr. J. A. RYLE (London) said that he had not a great deal of confidence in the evidence got with balloons and the other devices of the experimental physiologist. The piecing together of the wealth of information afforded by clinical observations was more important, but this very wealth was bewildering, and it was seldom that Nature produced a clean experiment. Taking as a type of abdominal pain that associated with spastic constipation, he showed how it might be systematically investigated by ten questions dealing with its character and degree, its spatial relationships, its temporal relationships—duration, frequency, and special times of incidence—and the factors, if any, which were to be regarded as aggravating or relieving its severity. His thesis, from his observations on colonic pain, was that the pain of disease affecting a hollow viscus was in that viscus and was a function of its musculature, that visceral pain may be localised with considerable accuracy, but that when inflammation or severe mechanical stress were lacking referred somatic signs and symptoms were generally absent. He considered that the pain of organic visceral disease was itself evidence of a functional disturbance, and might be closely simulated by the pain of a functional disturbance, without organic disease. He did not suggest that an abnormal degree of tonic shortening or hardening was the sole or even the usual cause of pain in the hollow organs of the abdomen, for there were stresses, not considered here, whereby tension in plain muscle-fibres might be exaggerated with resultant pain.

Mr. V. ZACHARY COPE (London) said that he had cast aside his five pages of typescript, as their matter had already been covered. He had three points he would like to emphasise: (1) Pain from some areas was very accurately referred. Thus the pain referred from the diaphragm should not be loosely described as "shoulder" pain—it was subclavicular, acromial, or supra-spinous according as the focus was anterior, medial, or posterior on the diaphragm, with symptoms due to the stomach, the spleen or liver, or the duodenum or enlarged glands. (2) Localisation by means of the parietes might be impossible. Thus he had himself experienced acute hypogastric (testicular) pain from an appendicular abscess, and had met the same reference of the pain in others. Hunger-pains, associated with the pylorus, might be due to a focus, God knows where! (3) He would remind us how much parietal sensibility varies in different areas. Thus pelvic peritonitis was much less painful and slower in developing pain than the upper abdominal type—the two areas might be regarded as "silent" and "demonstrative" respectively. He agreed with Mr. Morley that the viscero-motor reflex was a myth, the symptom being due to direct irritation of the parietal peritoneum. He had a feeling built on clinical observations that the viscera had a very much larger representation in the *left* side of the brain than in the right—he even estimated the proportion as ten to one! He felt that in the discussion the speakers had not sufficiently differentiated spontaneous pain from that elicited by pressure. In appendicitis, for example, the former was a general hypersensitiveness in the right iliac fossa, whilst the latter could be sharply localised but varied with posture and the like.

Prof. A. W. SHEEN (Cardiff) thought that pain was the last guide for a surgeon to use, and regarded tenderness as a much greater help. He felt very enthusiastic about sympathectomy, as introduced by Leriche for inoperable tumours. In answer to the really important question: Is a surgeon to operate for abdominal pain? he had followed up a large number of non-operated and non-diagnosed cases, and all but one—an obscure case of gastric crisis—were well and working. He referred to severe abdominal pain in erythema multiforme, and said that one of his most popular lectures dealt with 30 causes of abdominal pain in which the surgeon should by no means interfere. It would be a good thing if one could have in hospitals a border-line ward, in which *surgeon and physician could go round together.*

Dr. A. P. CAWADIAS (London) said that in a consideration of abdominal pain there were three elements to remember—the visceral, the nervous transmission, and the cortical perception, and that often the neurological and psychological points of view were as important or more important than the purely gastro-enterological. Too little stress was laid on the neuritis of the splanchnic nerve, which might be due to an acute infection such as dysentery or to a toxic factor such as alcohol or nicotine. The central perception element could be treated by local novocaine, or by counter-irritation of any kind to inhibit the pain, or by shock therapy. He would plead for a broader conception of abdominal pain, neurological and psychological as well as surgical.

Mr. A. R. FLINT (Leeds) briefly described a case in which, after total gastrectomy, there were incessant hunger-pains. (Dr. POULTON explained that there were contractions and relaxations in the jejunum as in the stomach and œsophagus.)

Replies.

In his reply, Dr. MAYO said that he had been struck by the wonderfully gentle way in which the speakers had treated each other, even where they had serious points of disagreement. It was the general view to-day that surgery was too much the surgery of sacrifice—sacrifices which would have been saved had patients, appreciating the significance of pain, gone earlier to their physicians. Medical discussions were still too much concerned with gross disease—too often treatment was expectant until there was something to sacrifice. Clearly food was implicated as a factor in the ætiology of most of these cases, and in the Mayo Clinic much attention was now being devoted to the allergies and food peculiarities. Referring to the Leriche operation, even this might only be successful for some months, and cases should be treated before such grave indications arose. "I *do dislike* the acute abdomen—laparotomy after laparotomy" were his closing words.

Sir FARQUHAR BUZZARD thought that in the case referred to by Mr. Flint he might be dealing with a form of "phantom stomach." He had been particularly pleased with Dr. Ryle's contribution to the discussion, but was shocked by Prof. Sheen. For himself he believed that we could learn far more by listening longer to our patients, and he would emphasise the danger of stressing the indications afforded by tenderness, since this was a symptom vitiated by fear.

SECTION OF RADIOLOGY AND RADIO-THERAPEUTICS.

EARLY DIAGNOSIS OF CANCER OF THE STOMACH.

Prof. Haudek's Address.

Dr. W. J. S. BYTHELL (Manchester) being in the chair, Prof. MARTIN HAUDEK (Wilhelminenspital, Vienna) opened a discussion on the value of X rays in the diagnosis of early gastric carcinoma. During the last decades there had been in Germany, said Dr. Haudek, an increase in the average duration of life from 38 to 57 years. From middle life onwards, cancer, next to cardio-vascular diseases, was the commonest fatal disease. In 35 to 40 per cent. of deaths from cancer the stomach was the site of the growth, and early recognition of gastric carcinoma was a most promising line of attack upon cancer. Now that X rays had been available in the diagnosis of cancer for 20 years, to omit their use in diseases attended by gastric symptoms was a professional error. Many thousands of cases of gastric carcinoma had been diagnosed by the aid of X rays, and the number of laparotomies at which incurable cancer was found had decreased (73·8 per cent. during 1901–14; 62·1 per cent. during 1915–25, Eiselsberg, Vienna). Unnecessary and merely exploratory laparotomies had also decreased in number, especially the latter. To the use of X rays also belonged some of the credit for the increase in the number of resections for carcinoma—from 22–40 per cent. between 1908 and 1924. But 60 per cent. of operations were still undertaken too late. Any estimate of the possibility of further progress—concerning which he was himself hopeful—must involve a consideration of present causes of failure.

There were, he said, three main causes of delayed radiological diagnosis of gastric carcinoma. (1) *The latent period*, during which the disease presented no symptoms. (2) *Delayed X ray examination*, due to latency and to non-recognition of the gravity of the local symptoms by doctor and patient alike. (3) *Faulty X ray examination.* At one time the difficulties of radiology were underestimated. Too much importance was still attached to apparatus, and too little to the operator by laymen, and unfortunately, by many doctors. X ray examination was sometimes undertaken by men with only a little technical training. The result of an examination depended far more on the skill of the investigator than on the quality of the apparatus. The X ray specialist should have a thorough basic knowledge of pathological anatomy and internal medicine. Similarly, physicians and surgeons who carried out their own X ray examinations must be familiar with general radiology, and if not certain of their findings must consult a radiologist of experience. X ray consultations were far too seldom requested. Screen examination without radiography was another fault in technique, especially in the diagnosis of carcinoma, where a study of the "relief pattern" of the mucosa (as seen in good X ray films) was essential. For each examination about half an hour was required, and no more than six to eight consecutive examinations should be undertaken. The investigation may require to be completed the following day. Superficiality and fatigue were inevitable if even an experienced radiologist was required to undertake 20 or 30 examinations in a few hours, as in some hospitals. The results might be only 10 per cent. worse, but what patient would like to be among the 10 per cent. in whom a cancer of the stomach was recognised too late?

Technique.—There was, said Dr. Haudek, no standard technique in gastric investigation. He commenced himself by taking an accurate history of the illness, as a frame into which the X ray findings fit. Before the abdomen was examined the chest was screened. The cause of symptoms hitherto attributed to the stomach might be thus shown to be aneurysm, pulmonary tuberculosis, malignant pleurisy, pulmonary metastases, or bronchial carcinoma. With the patient standing on a low footstool, the abdomen was palpated for increased tension of the recti, localised tenderness, or resistance. Four hours earlier the patient has taken for the motility test a meal of thick gruel containing 70 g. of barium sulphate. Apart from the large residues significant of pyloric stenosis, a small remnant might be visible as a "surface film" of an ulcerated carcinoma. The second meal consisted of about 300 c.cm. of a mixture just fluid enough to swallow, containing 120 g. of barium. The patient first drank one large mouthful, 20–30 c.cm., which was followed down the œsophagus. If there was any delay or dysphagia he gave a small gelatin capsule, containing one gramme of barium. If this, followed by a drink of water, passed undelayed through the cardia, malignant stenosis could be excluded, but the arrest of the capsule was of great service in the diagnosis of cancer of the cardia, whether originating there or in the stomach. When it reached the stomach the first mouthful of 30 c.cm. of suspension was dispersed by compression with Holzknecht's "distinctor" or a pad. The folds of mucosa were thrown into relief by a thin film of barium, and thus the whole stomach wall could be examined, unless retained secretion interfered (by dilution of the paste) with this study of the "relief pattern." Central shadow defects, or furrows between the lobes of a medullary carcinoma, led to a definite diagnosis of tumour. The borders of benign growths were circular and well defined. The stomach was then filled with the remainder of the suspension, and screened at different angles, the contour, the flexibility of the walls, and the peristaltic movements being studied. If in atonic, dilated stomachs the crescentic barium shadow did not reach the lesser curvature in spite of pressure, the patient was laid upon a couch on his right side for a few minutes and re-examined. He attached great importance to examination in the prone position for the study of peristalsis along the lesser curvature. A flat infiltrating growth on the lesser curvature might cause no disturbance of peristalsis along the greater curvature which alone could be studied in the erect position. In his opinion the examination of peristalsis on the lesser curvature (with the patient prone) rendered superfluous the expensive apparatus required for Fränkel's cinematography.

In the majority of cases Dr. Haudek found a single X ray examination to be sufficient, but if the motility test had shown retention of food or secretion, a second examination was required on the following day. Having taken only liquid food on the evening of the first examination the patient returned next day in a fasting condition, and before examination lay upon his right side for at least two hours, with the pelvis raised. The pylorus thus became the lowest point, and the stagnant contents were evacuated more completely than with a stomach-tube. About 50 c.cm. of very thick barium cream were then introduced into the empty stomach, and the examination of the relief pattern made as described; finally the gastric contour was examined with the full drink. If the method described failed, there was either pyloric stenosis, due to cancer or ulcer (which could be ascertained), or there was high-grade hypersecretion due to ulcer. To distribute the contrast substance Holzknecht's distinctor, or one or both hands were employed. The speaker did not use lead rubber gloves, relying on the thickness of the patient's body as a protective medium.

The number of very small growths discovered in the earliest stage was small. A much larger number of operable tumours had been sent to operation, but most numerous had been those in which inoperability has had to be reported. He showed on the screen a dish-shaped tumour which, with the stomach completely filled, might easily be confused with an ulcer niche. In the relief pattern, however, the folds of mucosa terminated abruptly before they reached the carcinomatous crater, whereas they converged upon an ulcer niche. Another slide showed an operable growth at the pylorus. The radiologist's interpretation and the histological report were in agreement that the lesion was a carcinoma, though at the macroscopic examination it had been assumed that an ulcer was present. Circumscribed scirrhus almost always originated on the lesser curvature just proximal to the pylorus, and the greater curvature was drawn towards the lesser as a "spigot" formation. In prepyloric ulcer and benign thickenings the lesser curvature was flattened, and the convexity of the greater curvature is maintained. Medullary carcinoma, even when near the cardia, was the most favourable type of tumour, both in case of diagnosis and operability. Characteristically it showed a central filling defect like a benign tumour, but the latter might sometimes be differentiated by its well-shaped edge, or pedunculation. The radiologist should never assume the responsibility of delaying operation because he considered a tumour as probably non-malignant. Another slide showed a commencing adenocarcinoma high up in the body of the stomach, clearly visible in the partly filled stomach, but impossible to demonstrate with the stomach completely filled. In no single clinically suspicious case in which he had excluded carcinoma during the post-war period had the disease, said Dr. HAUDEK, been later shown to exist. Erroneous diagnosis of cancer was most frequent in the pars pylorica, and the differentiation of ulcer and cancer was most difficult there because ulcers of the pars rarely show niches, and were often accompanied by considerable submucous œdema, which caused irregularity, and by spasm. Thirty per cent. of prepyloric ulcers underwent malignant degeneration compared with 3 per cent. in the pars media. He referred to investigations upon the significance of gastritis in early diagnosis of cancer (Orator). If it became possible anatomically to distinguish precancerous gastritis from that associated with ulcer, resection of precancerous gastritis would represent the early operation for carcinoma (Konjetzny).

Discussion.

Dr. A. E. BARCLAY (Cambridge) acknowledged the deep indebtedness of radiologists to Prof. Haudek, whose pioneer work had guided him from the outset of his radiological career. He recalled some early failures and early successes in gastric diagnosis, and emphasised that then, as now, he had learned to take nothing for granted—not even the correctness of an adverse operation report. Definite lesions shown in the radiogram can be overlooked at operation. He agreed with the opener in stressing the importance of critical study of the mucosal folds, and of the value of the sign of disappearance of the folds in carcinoma in contrast to their convergence in ulcer. He had not used the opaque capsule for diagnosing growth at the cardia, but used a bismuth bolus. He asked Dr. Haudek whether he could give an explanation of the rapid emptying often noted in early carcinoma wherever situated in the stomach. He felt strongly that re-examination by the radiologist in suspicious cases should be conceded far more willingly by both patient and doctor than was the case at present. A single examination, however painstaking, might sometimes leave a doubt, which re-examination would definitely confirm or dispel. He deprecated overloading the radiologist, especially in hospitals and clinics. Early diagnosis depended first, foremost, and all the time on the knowledge and skill of the investigator.

Dr. J. C. BULL (London) commented on the highly significant fact that in the post-war period the Opener had not had a single negative carcinoma *diagnosis disproved by operation.* He then showed slides illustrating spasmodic contractures simulating earliest carcinomata; in these cases operation or subsequent course had established their innocent nature. He had found belladonna, so strongly advocated by Carman, disappointing in abolishing these spasms. The speaker emphasised, from his own experience as a clinician practising radiology, that no single method was so valuable as the radiological in diagnosing gastric cancer.

Dr. GILBERT SCOTT (London) said he regarded Prof. Haudek as the patron saint of the direct method in opaque meal work; his technique should be standard for all routine work, not only for carcinoma. Dr. Scott himself had always advocated systematic radioscopic palpation with the small "white-wash" meal. Immediate complete filling was a common source of error. The rugae must be examined in detail. With regard to the surface film often retained on the carcinomatous surface, research should be directed to finding the most suitable consistency of *meal to cause such a deposit*; watery solutions often failed to give it. He deprecated taking a preliminary history, which was bound to bias the report. He examined first and took the history afterwards. He referred to the difficulty in distinguishing large chronic ulcers from carcinomatous ulcers; it was not his habit to make a diagnosis of carcinoma, but to report an organic lesion. Pyloric carcinoma with dilatation of the stomach showing paradoxical feature of ready passage of pylorus by contents indicated old chronic pyloric ulceration on which malignant disease had been subsequently grafted. The ulceration resulted in obstruction with dilatation, but when carcinoma converted the pylorus into a rigid tube obstruction was relieved. He thought the chief reason for delayed diagnosis was the latent period. He discarded indirect evidence, such as local tenderness, rigidity, and rate of emptying, if this were the sole evidence obtainable, and relied entirely on direct evidence. He hoped Prof. Haudek's paper would not lead the inexperienced worker to subject patients to unnecessary laparotomy on the strength of minute, imperfectly understood, variations of the normal contours. He asked what value he attached, in differentiating simple from malignant lesions, to the occurrence of peristalsis right up to the edge of the visible lesion. As regards operability, it was Dr. Scott's habit to confine himself to a statement of the extent of the lesion, leaving the question of operability to the surgeon; the operative findings were supplied him in every case.

Dr. W. H. ROWDEN (Leeds) said he found half an hour too little for an examination. He used a technique similar to Prof. Haudek's, and also insisted on the prone examination. He had found it a help to bring the tube close up under the patient in watching peristalsis in this position, since this exaggerated the size of the peristaltic wave. In taking serial pyloric radiographs the interval should be a minute or longer. Normal radiograms at such intervals never gave two exactly similar pictures, but serials at shorter intervals might do so even in a normal case. Like the opener, he had found an increase in the number of actual resections, indicating an improvement in early diagnosis. As regards pyloric obstruction, one point was of value in differentiating simple from malignant obstruction; obvious pyloric obstruction at the cancer age with a small stomach was invariably due to malignant involvement, with a large stomach it was almost invariably non-malignant.

The PRESIDENT had felt for some time that a *definite diagnosis of malignant disease of the stomach* ought to be obtained more frequently than in any other condition examined by an opaque meal. With careful examination and improved technique it should soon be possible to put the early diagnosis of gastric carcinoma on a very sure basis. He referred to the difficulties due to extrinsic tumours, particularly of the head of the pancreas, and instanced two such cases simulating gastric carcinoma.

Reply.

In reply, Dr. HAUDEK said the double meal method which he had introduced 20 years ago, with a six-hour normal emptying limit, had been an improvement on previous methods, but he had now come to rely upon direct signs. Alterations of emptying rate were of secondary importance, often purely functional. Rapid emptying, for example, could occur in many conditions, and could not be relied on for establishing early diagnosis of carcinoma. The rapid emptying seen in carcinoma, to which Dr. Barclay had alluded, he ascribed to rigidity of an infiltrated pyloric end, in which, though the lumen was reduced in calibre, there was a failure of the pylorus to close. Six-hour residues were commoner in ulcer than in cancer, and usually larger. He warned against over-estimating the importance of rapid emptying and delay. Dilated stomach was common in ulcer, rare in cancer. Hyperperistalsis, a common functional disorder, was of little value in diagnosis, but anti-peristalsis usually signified an organic lesion. Most important was the *interpretation of normal peristalsis.* For this the prone position was essential, and he thought it a fallacy in Fränkel's cinematographic method that the standing position was used by that worker. This position failed to show the highly important lessercurvature peristalsis. He agreed with Dr. Bythell that extrinsic tumours might cause difficulties, but the examination of the mucosal relief and the pliability of the gastric walls generally excluded such conditions. Dr. Rowden was in error in thinking 20 minutes to half an hour was all he required for a gastric examination. *This was an average figure*; many carcinomas were diagnosed in the first few seconds. In a difficult case unlimited time was allowed. As regards a case history, he often had to do without it owing to language difficulties in a mixed population; its importance lay in suggesting some further examination when the stomach was negative. The X ray examination only made an anatomical diagnosis. For the full diagnosis the history was necessary, and Dr. Haudek said his colleagues often welcomed his general opinion of the case based on examination of many thousand cases.

SECTION OF OCCUPATIONAL DISEASES.

OCCUPATIONAL DUST.

Dr. W. F. DEARDEN being in the chair, the discussion was opened by Dr. J. C. BRIDGE, H.M. Senior Medical Inspector of Factories, who remarked that it was in Manchester he joined the Factory Department as a medical inspector, one of his earliest duties being to inquire into an outbreak of "weavers' cough" at a spinning mill. The works of Arlidge and Oliver, he said, were full of valuable mortality statistics for various industries, and Collis, in his Milroy lectures for 1915, dealt fully with the effect of dusty occupations and mortality-rates, emphasising the effects in particular of the dusts of free silica (SiO_2). The inquiry of Dr. Dearden, Milroy lecturer in 1927, into the health of workers in humid cotton sheds and the printing industry, had been carried further by Dr. Bradford Hill.

For himself, said Dr. Bridge, he could do little but indicate some of the more common forms of injury to health produced by occupational dust. He proposed to divide such effects into two arbitrary groups, realising fully that some might fall into both groups, and that others, in the light of better knowledge, should be included in both. These were: Dusts which exercised (*a*) a general toxic effect; (*b*) a localised effect, whether (1) internal, or (2) external.

Group A. Dusts: General Toxic Effect.

This group consisted mainly of the dust of certain metals, and chiefly their salts, which produced a definite syndrome of symptoms. Of these probably the most important, and one which was still met with most frequently, was lead and its compounds. *Lead* poisoning still figured prominently in the notifications made to the Chief Inspector of Factories. (Dr. Bridge gave comprehensive tables of case-incidence and mortality for various industries.) To one point in connexion with lead excretion he drew special attention. Kehoe and other American observers found that lead was excreted in measurable quantities in the urine of normal healthy persons who had not been exposed to any known risk of lead absorption. These findings were confirmed by Prof. Chaston Chapman, and were important because the presence of small quantities of lead in the urine had been regarded as confirming the diagnosis of lead poisoning in a lead worker.

Arsenic.—The classical symptoms due to the inhalation of dust containing arsenical compounds did not often occur in industry. In general, the effect of arsenical dust was manifested by localised affections of the skin.

Manganese.—In 1922 Dr. J. R. Charles, of Bristol, drew the attention of the Department to two cases of manganese poisoning affecting men employed in grinding manganese ore. Other cases had been reported in America in the manufacture of manganese steel. (Dr. Bridge gave the symptoms of manganese poisoning in detail, and dealt with poisoning by zinc, cadmium, and the nitro and amido derivatives of benzene.)

Organic Dusts.—Dusts might act as carriers of toxic substances or organisms, and produce symptoms of a general character. Fur dust after carotting—that is, painting with nitrate of mercury—had produced mercurial poisoning. Wool sorters' disease was due to the inhalation of dust carrying spores of the anthrax bacillus. Of special interest to Lancashire was the condition known as "weavers' cough," which might be due to the inhalation of the spores of a mildew. Closely allied was the cough affecting men working in malthouses. No doubt there were other dust-borne diseases due to the presence of a fungus.

Group B. Dusts: Localised Effects.

The most important and widespread forms of localised internal disease produced by dusts were the various forms of pneumonoconiosis, of which silicosis was the most important. The recent scheme for compensation under the Various Industries (Silicosis) Scheme gave some indication of the widespread nature of the industries in which dust containing free silica occurred. Dr. Bridge mentioned the fine type of fibrous pneumonoconiosis produced by silicates and other minerals, and the effects of the inhalation of coal dust upon trimmers. In time, he said, with a more complete survey of workers exposed to particular dusts, it might become possible to determine the particular form of dust by the character of the fibrosis to which it gave rise.

Vegetable Dusts.—Of the effects of these on the lungs little or nothing was known, but Dr. Middleton concluded that the dust in the case of wheat, barley, rye, and oats contained hairs derived from the grain which on *a priori* grounds appeared to be capable of causing irritation of, and inflammatory changes in, the respiratory passages. Dr. Bridge quoted the case of a woman employed for 25 years at a bench where she had been exposed to inhalation of pure tobacco dust, and who suffered from loss of sight. He also drew attention to Dr. J. B. Duguid's article (THE LANCET, 1927, ii., 111) on the incidence of intrathoracic tumours in Manchester.

Turning to the localised external diseases produced by occupational dust, there were, said Dr. Bridge, few if any dusts occurring in industry that would not produce in certain individuals an inflammatory condition of the skin. This not only made it difficult to decide whether or not a dermatitis was of occupational origin, but threw doubt, in many cases, on the actual causal agent. From his own experience the dusts which appear to exert the most rapid and severe conditions were the nitro compounds of benzene and its homologues—for example, dinitrochlorbenzene, picric acid, paranitraniline. Of simple compounds the sodium and potassium salts of chromium and the caustic alkalis produced not only skin lesions, but ulceration of the mucous membrane and septum of the nose leading to complete perforation. The absence of untoward symptoms following such definite destruction of the internal nares was a matter of surprise. Cancer of the skin was produced wherever pitch dust was generated, and the connexion between cancer and arsenical dust was well established. The oldest form of cancer of the skin—namely, that of the chimney sweep—still occurred. Dr. Bridge concluded by saying, "While once the masters of cure, we are now, or ought to be, the slaves of prevention. A dust-free industry may be ideal, but it should be our goal."

Asbestos Dust.

Dr. W. E. COOKE (Wigan) read a paper on asbestos dust, and the curious bodies found in pulmonary asbestosis. Asbestos, he said, was woven into cloth before the time of Herodotus 450 B.C., but pulmonary asbestosis dated only from A.D. 1900. After describing the chemistry and microscopical appearances of asbestos fibre and dust, and the presence of large particles of the dust in fibrotic and necrotic areas of the lung, he detailed further experimental work on the curious bodies found in this disease. His explanation of their formation was that fine spicules of asbestos, by mechanical action on the bronchioles and alveoli, caused either minute extravasations of whole blood or serous exudates which enveloped them. Interaction took place between the plasma proteins and the soluble fraction of asbestos with adsorption of colloidal aggregates on to the spicules. In support of this he showed specimens containing a slender filament of biotite upon which colloidal matter had been deposited. As these bodies had been found in every autopsy in this disease, and as the only mineral that could possibly produce them was asbestos, their presence in any numbers was pathognomonic of pulmonary asbestosis.

Dr. A. C. HADDOW (Leeds) described the clinical aspects of asbestosis, and quoted a case in which the curious bodies were found in a man who was not employed in the industry, but who lived next door to an asbestos factory. This result was confirmed by Prof. J. M. Stewart (Leeds).—Dr. W. BURTON WOOD (London) showed X ray photographs of cases of pulmonary asbestosis and compared the picture with that of silicosis.—Sir THOMAS OLIVER (Newcastle) also spoke on the clinical aspects of the disease.—Sir THOMAS LEGGE (formerly H.M. Medical Inspector of Factories) said there could be no doubt of the seriousness of asbestos poisoning among the workers in that material. The idea that nothing but free silica dust would set up fibrous changes in the lungs had had a very bad effect, and the foregoing papers showed how important it was not to underrate other kinds of dust such as asbestos. He hoped to see asbestosis added to the list of diseases for which compensation could be obtained.

Reviews and Notices of Books.

CARDIOLOGY.

The Heart in Modern Practice. Second edition. By WILLIAM DUNCAN REID, A.B., M.D., Assistant Professor of Cardiology, Boston University. London: J. B. Lippincott Company. 1929. Pp. 460. 25*s.*

THE second edition of this text-book differs from its predecessor principally in the addition of nine new chapters dealing with the cardiac arrhythmias. This is hardly an improvement, for, as the author admits, it completely alters the balance of the book, which was its chief merit. One of the greatest difficulties of a student is to get a good sense of proportion and to see the various facts of medicine in their true perspective. For many years heart murmurs were the centre of attraction, more recently they have been superseded by the arrhythmias; but now that these are beginning to fade into the background and find their true level, it is no longer desirable to give them such a prominent place. Among the many minor alterations are the sections dealing with circus movement and coronary infarction, which constitute valuable additions. The electrocardiograms used as illustrations are clear and well reproduced, though we prefer actual polygraphic and sphygmographic tracings to diagrammatic ones. The numerous references to recent original papers will be appreciated by those who wish to study each subject more deeply; but compared with the more modest first edition this volume is on the whole disappointing.

The Pressure Pulses in the Cardiovascular System. By CARL WIGGERS, M.D., Professor of Physiology, Western Reserve University, Cleveland, Ohio. London: Longmans, Green and Co. 1928. Pp. 200. 14*s.*

IN cardiovascular mechanics the history of the development of the instrumental method of investigation provides frequent examples of erroneous conclusions resulting from the failure of workers to recognise mechanical artefacts. As one instrument supersedes another, new features make their appearance in the records. Often these have been attributed to the fundamental processes under investigation, when in reality they have been produced by the physical properties of the apparatus. In recent years it has been the aim of experimentalists to devise instruments in which inertia is reduced to a minimum. Dr. C. Wiggers, being a pupil of Otto Frank, has naturally devoted his attention especially to optical methods of registration, and has collected in this monograph his own observations on this subject and those of other workers. The two opening chapters are devoted to a critical review of the instrumental artefacts which vitiate or modify the form of the records obtained. There follows a series of chapters dealing with the pressure changes and sequence of events within the heart, arteries, and veins, and a consideration of the various factors such as heart-rate, venous filling, and aortic resistance which may modify the normal sequence of events. The author points out that ventricular as well as auricular systole is a fractionate process, and considers the bearing of this fact on the interpretation of the intraventricular pressure curves. In the final chapter he deals with the way in which the commoner types of arrhythmia may modify the mechanics of ventricular systole. To the clinician who lacks a thorough grounding in physics it may prove stiff reading, but it should be read not only by the physiologist, but by all those who are especially interested in the study of heart disease, since so many of the problems considered have a direct bearing on the practice of medicine.

This book forms one of the Monographs on Physiology, formerly edited by the late Prof. Ernest Starling, which are intended to review the present position of our knowledge in those departments which have advanced most in recent years.

Heart Disease in Childhood. By H. B. RUSSELL, M.D., M.R.C.P., and C. K. T. HAMILTON, B.M., M.R.C.P. London: Constable and Co., Ltd. 1929. Pp. 104. 7*s.* 6*d.*

Heart Disease in Childhood is such an attractive title that it is a pity the authors have not kept more closely to their subject. Such descriptions as that of the electrocardiographic method, for example, cannot, by any stretch of the imagination, be legitimately included; the book suggests an elementary treatise on general cardiology which has been modified in order to render it applicable to the cardiac affections of childhood. Rheumatic heart disease is discussed in considerable detail, but the subject of congenital lesions is dismissed in eight pages. It is surprising that the old hypothesis of "back pressure" should still find a place in one of a series of Modern Medical Monographs. On the whole it is our impression that the authors have inserted quite a lot of irrelevant matter, while they have failed to make the most of their material.

What you should know about Heart Disease. By HAROLD E. B. PARDEE, M.D., Assistant Professor of Clinical Medicine, Cornell University. Philadelphia: Lea and Febiger. 1928. Pp. 120. $1.50.

HEART disease to the lay mind is apt to be associated with the idea of sudden death and it is often difficult for people to realise that in its milder forms it is not necessarily progressive, and may, in fact, be compatible with a fairly active life. The object of Dr. Pardee's little book is to elaborate this thesis in language intelligible to the general public, to explain the nature of heart disease and the reasons for the various therapeutic measures employed. By so doing the author hopes to achieve a more intelligent coöperation between patient and doctor and so to enable them to work together to the best advantage. There is an admirable chapter on exercise and rest and the question of diet is fully discussed. Dr. Pardee gives perhaps too optimistic an impression of prognosis, but that is excusable, for he is deliberately out to counteract undue pessimism. His book will undoubtedly be of real value to many sufferers from heart disease, for while avoiding technical terms he has succeeded in giving an accurate, up-to-date and well-balanced account of its more important aspects.

QU'EST CE QUE LA MÉDICINE?

By E. RIST. Paris: Masson et Cie. 1929. Pp. 235. Fr. 25.

THIS is a thoroughly interesting book of essays, displaying a wide range of general and special knowledge, while its pages are full of the love of history and the appreciation of art. The essay on the Hippocratic oath is one of the best sermons on the sanctity of medical confidence we have read, and the accompanying essay on the moral responsibilities of the doctor is a direct development of the old Greek's words. The essay on the diagnosis of the diseases of the chest before the methods of percussion and auscultation were applied—the dates of these two classic methods of exploration being 1761 (Auenbrugger) and 1819 (Laënnec)—is a sound study, while Les Débuts de la Percussion is a development of this essay and leads up to a general chapter on the progress of our science. Here is a serious lecturer at his best—wise, but not didactic, not flippant, but never dull.

MADNESS IN SHAKESPERIAN TRAGEDY.

By H. SOMERVILLE. With a preface by WYNDHAM LEWIS. London: The Richards Press, Ltd. 1929. Pp. 207. 6s.

Mr. Somerville, in a series of interesting essays presenting modern as well as accepted views, deals with the old subject of madness as represented in Shakesperian tragedy, stating his conclusions well and justifying them, where he can, by references to the text. The characters selected for comment are, save perhaps one, familiar to the whole world—their words and their deeds may be said to form a part of universal education. Such characters are Hamlet and Ophelia, Macbeth and Lady Macbeth, Lear and Goneril, Othello, Brutus and Constance, the last being the only one of whom many things cannot be immediately recalled save after a recent reading of "King John." She is best remembered by the terrific words in which she courts death, words which, as Mr. Somerville points out, could not have been used by a person so mentally destroyed. But even though there may be a difficulty in reconciling the coherency of language with the disorganisation of mind, the picture of a battered mentality is vividly presented; and here the author points out that quite early in his creative activity Shakespeare realised the value of insanity as a means for the exhibition of the excessive emotion necessary to the violence of his tragedy. He might have added that in Elizabethan days the insane lived largely with the sane, and were, therefore, more easy subjects for study than they became when segregation was the rule. Constance is selected for particular comment because the rising tide of insanity can be watched throughout a story, at the commencement of which she is perfectly sane; thus we have a fine exhibition of the early growth and development of acute mania. To Hamlet's madness he thinks the type manic depressive most nearly corresponds; Macbeth he labels a paranoiac; Lear, a victim of attacks of acute mania, who, if he had lived, would have been a hopeless dement; Ophelia has the temporary mental overthrow of the girl madly in love; Timon is a sound typification of megalomania; while Brutus's mental breakdown is found convincingly to have many features common with that of Macbeth. Goneril is described as a mental monstrosity, the words implying that anyone so foully wicked could be nothing but mad, while Lady Macbeth more or less escapes analysis—her response to horrible circumstances is a lapse into mad criminality.

The various views in the essays may be exactly regarded, in the author's words, as "attempts to explain some of the difficulties occurring in the speeches, as well as those arising out of the strange and puzzling behaviour of the principal characters during their attacks of insanity." The explanations are for the most part satisfying; they could not be expected to cover the field.

THE MODERN DANCE OF DEATH.

The Linacre Lecture for 1929. By PEYTON ROUS. London: Cambridge University Press. 1929. Pp. 51. 2s. 6d.

A MODEST little book which is worth careful study and a good deal of reflection. It should be widely read by the hygienist on the one hand and the experimental pathologist on the other. We flatter ourselves that medical science has enormously reduced the incidence and fatality of most diseases and we are apt to forget that the body is just where it was; it has now just the same potentialities and limitations as it had, when infectious diseases left a much smaller porportion of the population to realise that there was a natural end. We dance with death now as we did, but less reluctantly—for it is towards the end of the evening and we are getting tired. Such in brief is the tenour of Dr. Rous's sermon. As he gave it, it is a brilliant commentary on life and individuality, full of shrewd discourse about the hard facts of experimental medicine to which he has himself made such notable contributions. Those who do not care for the philosophy will find the pathology of the best.

STONES, HILLTOPS, AND THE SEA.

By RUTH ALEXANDER. London: Alston Rivers. 1929. Pp. 272. 12s. 6d.

THIS is a record of a month's travel enjoyed by the author in company with some twenty other people. The party toured the Eastern half of Yugoslavia in two motor char-à-bancs, and met with many small adventures and many large opportunities of learning what life is like in a very unfamiliar part of Europe, opportunities which have been well used in this book. The journey covered Slavonia, Croatia, Bosnia, and Herzegovina, still replete with the signs of Turkish rule, Montenegro, and Dalmatia, with its Italian enclave, and Miss Alexander has noted with discriminating enthusiasm and humour the extremes of fertility and barrenness manifested by the landscapes and the variety of religious tongues, and clothes offered by the populated centres. This is a gay account of a jaunt which, it can be gathered, was thoroughly successful in the event though often trying in its experiences. Some of the many picturesque scenes are reproduced from photographs supplied by two of the author's fellow-voyagers, Dr. G. A. Grierson and Dr. V. G. Ward.

AN OUTLINE OF ENDOCRINOLOGY.

Second edition. By W. M. CROFTON, B.A., M.D., Lecturer of Special Pathology, University College, Dublin; Pathologist, Dr. Steevens' Hospital, Dublin. Edinburgh: E. and S. Livingstone. 1929. Pp. 163. 8s. 6d.

THIS is the second edition of Dr. Crofton's handbook of endocrinology, originally published in 1924. There are several additions to the text, notably a chapter on the liver chiefly dealing with pernicious anæmia (which, in spite of Minot and Murphy's valuable work on liver treatment, should surely not call for comment in a handbook devoted to endocrinology), and a chapter on recent advances. Many of the views expressed in this chapter are drawn from the author's own experiences, which appear to be so divergent from current medical opinion that they cannot be accepted without reserve. Nevertheless, there is much which is of interest in this book, though flights of fancy such as the following (p. 149) are scarcely to be commended to a serious student of medicine: "There is apparently no gland yet developed that will enable man to grow wings. Must we wait for the millennium until such a gland of internal secretion develops?" Perusal of this book leaves the impression that this happy state can hardly be long delayed. In the meanwhile the medical student interested in endocrinology would be well advised to follow the teaching of more generally accepted text-books of medicine.

THE LANCET.

LONDON: SATURDAY, AUGUST 3, 1929.

MILDER VACCINATION.

WHETHER post-vaccinal encephalitis is directly due to vaccination or whether it can be ascribed to a concomitant infection must be considered unsettled, though it might be argued that the evidence in favour of vaccinal encephalitis is at least as strong as that which is regarded as establishing the ætiology of some other diseases. The fact remains, however, that the number of cases of encephalitis following vaccination appears to be increasing, and recent inquests on such cases have caused a good deal of concern among the public. The increase is perhaps only apparent. It may be that in the past mild cases were not recognised for what they were, and that the association of fatal cases with vaccination was disregarded; but this does not alter the situation for the layman who sees in vaccination sinister possibilities which he had never before contemplated, and who is troubled by a suspicion that the knowledge of these dangers has been withheld from him. The suspicion is void of foundation, for it is only within the last six or seven years that the nervous complications of vaccinia have been recognised in medical circles; within that time, moreover, the Ministry of Health has appointed two distinct committees to consider various aspects of vaccination, and their reports were published together a year ago. The final recommendation of the Rolleston report (which we endorsed warmly at the time [1]) was that steps should be taken to impress upon the public mind the nature and purpose of vaccination, for which the report affords a body of accurate and unbiased information. Unfortunately this recommendation of the Committee has been ignored. No real attempt has been made to instruct the public on the nature of vaccination; to explain its advantages; to acknowledge its complications; and to discuss whether, on the whole, it is to be recommended.

The layman of to-day is too much interested in medical matters and too much alive to their importance to be impressed by mere dogmatic statements. Simply to assert that universal vaccination is necessary in the interests of the public health, and that the direst results are likely to follow its discontinuance, is not to convince him. He requires a reasoned argument and will not be satisfied with anything less. The situation is not rendered any easier by the fact that alastrim has been evident in this country for the last decade and has by its mildness done much to rob the name of small-pox of its terrors. It is true that from time to time there are outbreaks of virulent small-pox with a high proportion of fatal cases, but energetic action by the health authorities has hitherto kept them in control and they have scarcely served to remind the public what a dreadful scourge the disease was in this country not so many years ago. On the other hand, some hundreds of cases of alastrim are notified as small-pox every year, most of which are no more severe than simple chicken-pox. It is perfectly reasonable that the layman should say: why, if this is all that small-pox means, should I worry about vaccination, which apparently is itself more dangerous than the disease from which it is supposed to protect me? It is no good answering that this mild type of small-pox may at any moment change to the virulent form, for this is probably not true; American observations seem to show that for 20 years alastrim has bred true and has remained relatively innocuous. The right reply is that for all practical purposes alastrim differs so much from classical small-pox as to be a distinct disease, and that its mildness does not justify us in neglecting to take proper precautions against the more malignant form of small-pox.

We are left then with the question what precautions the profession should advocate in the circumstances of to-day. There can be no doubt that in an epidemic of severe small-pox the public would accept vaccination without much opposition, but as we pointed out two and half a years ago [2] there is enough sense in the average man's objections—when supplemented by the nonsense of the antivaccinists—"to make universal and full vaccination of infants (as theoretically enforced by Parliament) impracticable in this country at the present time." The first alternative to universal protection, we said, was to let small-pox take its course, offering vaccination to those who preferred it. The second was to modify our methods of vaccination so that sensible people would have no reason to fear and dislike them. The third was to abandon universal vaccination altogether in favour of the effective treatment of contacts in face of an epidemic. Criticism might be lessened, we pointed out, "if such vaccination aimed at conferring only brief and temporary immunity, and it is theoretically possible to check the progress of an epidemic by using an antigen producing symptoms so far negligible that popular prejudice would soon fade away." In the same article we quoted a method suggested by Dr. PARLANE KINLOCH for milder vaccination in infancy, and a few months later we published an account of American views and practice [3] which included a description of means whereby the least possible "take" may be secured. Meanwhile the Rolleston Committee has made its definite recommendation that a trial should be made of vaccination (or revaccination) in one insertion with a minimum of trauma.

In the B.M.A. discussion reported on p. 223 considerable dissatisfaction was expressed with the quality of the lymph available for the use of private practitioners, and from more than one quarter the demand was expressed for the universal supply of Government lymph. It was claimed that the lymph of private firms was unequal in its action, at some times failing to produce reactions, and this is probably true. But the statement in one of the proposed resolutions that in some vaccinations the health of the patient is seriously affected is surely far more significant than the complaint that certain lymphs are ineffective. As the Vaccination Committee pointed out, unsuccessful vaccination is very often due to faulty technique; but an excessive reaction suggests that the virus is too potent or the dose administered too great. It is probable enough that the method of four insertions officially advocated in this country gives the most efficient protection against small-pox, but we have ample evidence that its use is occasionally associated with severe local and general reactions, and we have the definite opinion of the Rolleston Committee that a different procedure should be tried. American and Canadian results suggest that vaccination and revaccination in one insertion is efficient, and though the actual duration of the immunity conferred is, of course, still uncertain, the Committee had excellent grounds for believing that satisfactory results would be obtained by primary vaccination in infancy, with revaccination on entering and leaving school. The infantile vaccination is undoubtedly of paramount importance. When carried out by the modified method its immediate effects are negligible, whereas all the evidence goes to show that if vaccination is postponed till the school age or later its dangers are definitely increased. The local reaction is greater and it is noteworthy that an overwhelming proportion of recorded cases of post-vaccinal encephalitis have occurred after infancy.

---

[1] THE LANCET, 1928, ii., 234.

[2] Ibid., 1927, i., 238.

[3] Ibid., 1927, i., 671.

Another important recommendation of the Rolleston Committee was that experiments should be made to determine if it is feasible to reduce the potency of the lymph without impairing its efficacy. We now realise that vaccinia is not only a local disease; the virus is disseminated throughout the body, and the question of the dose inserted obviously requires close study. It is probable that the lymph now in use is considerably stronger than necessary, and possibly the occasional serious sequelæ of vaccination would disappear altogether were a weaker lymph employed. Repeated but less energetic application of a more dilute lymph is likely to be the method of vaccination in the future. It offers adequate protection while at the same time it minimises risk. Vaccination can never be popularised while accidents are common enough to cause complaint in medical circles. Without doubt the public should be widely instructed in the necessity for adopting universal prophylaxis against small-pox, but at the same time we must ensure that vaccination itself is robbed of its terrors.

◆

THE REPORTS OF MEDICAL REFEREES.

It has been often remarked that a disproportionate amount of workmen's compensation law is made or declared in cases which originate in Scotland. An instance is furnished by the recent decision in the House of Lords in the case of Burrows *v.* Wilsons and Clyde Coal Company, in relation to the *reports of medical referees.* The *judgment of the* Lords firmly upholds the finality status of these reports, and at the same time the decision contains *useful hints for doctors who may be called upon to* act as referees.

In the case referred to the moving parties were the employers, and their object was to have the compensation ended by a declaration that the man had made a complete recovery. Their efforts were made on three separate occasions with substantial intervals of time, suggesting that the referee was proceeding in a strictly judicial spirit and was exercising a severely impartial judgment, as indeed might fairly have been assumed. At the first and the second attempts the employers failed, but after the third examination the medical referee reported that in his opinion the workman had completely recovered from the accident, and that his condition was such that he was fit for his ordinary work. Now the Act says that the report shall be conclusive—things must have an ending, and a county court judge is not qualified, nor probably has he the time, to sit in order to review the technical opinion of a medical expert, and to uphold or reject it on the balance, in his mind, of medical evidence from both sides. And anyhow such procedure might seem to justify appeals to higher courts on purely medical issues, which in most cases would be regrettable. But what happened was that the workman tabled in the county court at Hamilton a specific allegation of later symptoms, said not to be observable on such an examination as had been made by the medical referee, and which, it was alleged, pointed to a distinct risk of the disease recurring from the effects of the same accident. The workman did not, indeed, ask the county court judge to hear evidence on the subject, but he did present alternative suggestions. These were that either the report should be sent back to the referee for reconsideration, or that the order to be made should be one only suspending payment of compensation. The employers, on the other hand, stood upon the finality quality of the existing report, and claimed an order ending compensation. The county court judge took the employers' view and ended compensation. Then the workman appealed to the High Court in Scotland, and that court practically took the workman's view. The President of the court regretted that the man had not moved the county court judge himself to inquire into the allegations of risk of recurrence, and the court decided to send the case back to the county court judge for that purpose. No such step has ever before been taken, and in view of its general importance the employers took the case to the House of Lords. The result has been to restore the county court decision and to declare compensation ended. Lord Dunedin censured the step proposed to be taken by the High Court in Scotland as a *grave* disturbance of the administration code of workmen's compensation. Of that code two essential features are that a medical referee is final on medical facts, and the county court judge, as arbitrator, is final on all other facts.

No doubt it is a matter of temperament whether a medical man will or will not welcome the view that from his report as medical referee there can be no appeal, and that no cavilling at or contradiction of the report is even to be listened to. This latest decision in the Lords makes clear that, when the Act says that the report is conclusive, it means exactly what it says. This decision, then, conveys a lesson not to be forgotten. The quality of finality attaches only to an unambiguous report. This matter has been previously dealt with in these columns at length (*vide* The Lancet, 1929, i., 402), the occasion being the observation of Lord Sands in a judgment delivered in the Scottish Court of Appeal *in a case* similar somewhat to that under discussion. The report of the referee is no place for recording the considerations, reservations, and pros or cons on which the medical opinion has been arrived at. The problem may be difficult but an unambiguous solution must be put forward. A new feature was introduced by Lord Dunedin's *speech. Before this* case we should have said that the report must be unqualified, and as a general matter we say that still. But it is clearly contemplated that it is permissible for, and may be the duty of, a medical referee to report a complete recovery combined with—or ought we to say qualified by?—a risk of recurrence of the disease or of the effects of the injury. Is this another case where lawyers and doctors see things differently? A medical man would probably say that either there is complete recovery or there is not, and that if the ind [illegible] the accident has left effec [illegible] a recurrence of the condition, then there is not complete recovery. What appears to be really in view is whether the workman is again fit for the full exercise of his former trade functions. There will probably be agreement that that stage might be reached, and yet a medical man might see the prospect of a recurrence of the injured condition. Lord DUNEDIN clearly holds that a report of complete recovery with that qualification is a competent form of report, and that the consequence (with which, however, the medical man has no concern) is that compensation will be suspended and not ended. In this way this latest case may open a new chapter of difficulties. Obviously, a mere surmise or general suspicion that the existing state of matters may issue in recurrence will not be a proper exercise of responsibility. The attitude must be much more definite than that. Yet the medical referee is neither bound nor entitled to seek relief by stating detailed medical data, thus in effect throwing on the county court judge the responsibility of decision. Further, there might be a class of case in which, while the man is able to work as hard as ever, the fact of his doing so will bring into operation or accentuate the factors tending to recurrence. In such a case could it be reported that there was complete recovery at all? This class we have imagined, but it assuredly exists and introduces issues of real importance. If complete recovery be reported, with a rider added upon risk of recurrence, the best that the man can hope for is that compensation will be suspended; that is to say, he will in the meantime, and until recurrence, receive no more compensation. Whereas, if the true view is that in such a case it is not proper to report any form of complete recovery, then the man will continue to draw compensation, full or partial, as the case may be.

◆

THE CORRELATION OF CANCER STATISTICS.

THE radiological treatment of cancer has been accorded greater publicity than any other modern therapeutic method. The community has been invited to subscribe—and has subscribed—immense sums for the purchase of radium and for research into the application of radiological methods to cancer. The lay press has assured its readers that this line of work offers the most promising hope of a successful attack on the most dreaded disease. Experts have adduced satisfactory results in different clinics all over the world, and have shown that these results in certain regions of the body compare favourably with those obtained by surgeons. An effort is now being made on international lines to exploit this new weapon to the full and to prevent its abuse. The Cancer Commission of the League of Nations, realising the world-wide significance of the development in radiotherapy, appointed a subcommission to gather and collate information on methods and results. Unfortunately for this purpose the practice of radium therapy—the quantity of radium salt used, the shape of the applicators, the method of application, and the period during which the exposure is allowed—varies in different clinics, quite independently of the adjustment necessary to adapt general rules to a particular lesion in a particular patient.

The region of the human body first selected for investigation was naturally the genital tract of women, since the results after a period of years from all clinics are impressive. The subcommission entrusted to an executive committee, consisting of Dr. J. HEYMAN of Stockholm, Dr. A. LACASSAGNE of Paris, and Prof. F. VOLTZ of Munich, the task of collecting detailed case records from the three large clinics with which they are respectively connected, in the hope that these might be correlated. The report of the subcommission, which has just been published, forms a document[1] of great interest. Its most outstanding feature is, paradoxically, its failure to achieve its object. The subcommission had intended, from a study of results combined from these three centres, to draw up statistical data which would form a guide to radio-therapeutic treatment. Dr. JANET LANE-CLAYPON spent much time and labour on an attempt to produce this analysis, but was forced to the conclusion that the methods employed in the three clinics and the classifications of stage of disease differed in such essential particulars, and that the data of after-history were set out so inconsistently that any attempt to correlate the three sets of figures could only cause misunderstanding. It is not yet possible, in fact, for an unbiased statistician, from the material provided, to express in figures an opinion on the exact value of radium in treatment, or on the best technique for applying it. But it is clear that if radiological methods are to be explored and improved the experience of the big clinics must be available for smaller and younger foundations, and the subcommission have, therefore, taken steps to clarify the position. They have drawn up, with great care, a set of rules for the classification of the different varieties of utero-vaginal cancer, for the grouping of growths into different stages, and for the essential statistical data and the method of calculating results, and have elaborated a scheme for describing the details of technique. They have also designed a standard international case-record with a diagram for marking extent of growth, which has already been adopted by the three clinics at Stockholm, Paris, and Munich, and which will, it is hoped, be adopted by all other institutions using radiological methods. Five years hence, therefore, there should be a body of strictly comparable statistics from all parts of the world. From these it should be possible to decide with reasonable accuracy which methods are giving the most satisfactory results.

Though the achievement of the main object of the subcommission has had to be postponed, the illustrated accounts supplied by the three members of the executive committee, which form the bulk of the report, will certainly encourage those who look to radium and X ray treatment as the hope of the future in gynæcology. The results obtained show a steady improvement year by year. It is, however, obvious that the details of dosage and method of application must be most carefully considered and adjusted if the end-results are to be satisfactory. The increasing use of radium by practitioners who are not fully instructed in its technique offers a serious threat of abuse. The inexperienced doctor may rest content with transitory improvement in cases which he ought to cure, or may apply an inadequate or excessive dose by a method which has been discarded as unsatisfactory. No one who is unable to spare time to attend such practical courses as those offered by St. Bartholomew's or the Westminster Hospitals, or to work for a period at radium clinics, should attempt to treat patients himself. The fact that an international effort to frame, if not a code of rules, at least an indication of preferences, has failed, is not a warrant for daring experimentation by individuals even more ignorant of the physical and physiological forces thus harnessed than are the experts. The danger of the widespread advertisement of radium in the treatment of cancer is undoubtedly its casual adoption in private practice by men who would not try to perform an intricate surgical operation. With the establishment in all countries of convenient treatment centres in connexion with hospitals this danger should cease. It is probable that the study of records compiled on a comparable basis will lead to a standardised technique, but it is unlikely that this will ever be adapted for the use of those without special training.

Annotations.

"Ne quid nimis."

METROPOLITAN ASYLUMS BOARD.

THE annual report[1] of the Metropolitan Asylums Board, which has just come into our hands, reviews the work of the Board for the year which ended on May 31st last. The Board was established in 1867, to combine the unions and parishes of the metropolis, for the purpose of establishing "asylums" for the reception and relief of the sick, insane and infirm, and the present is the thirty-first report which sets out the discharge of these functions. It will be the last review of a complete twelvemonth report to be issued by the Board, for on April 1st next the whole of its functions will be transferred to the London County Council, and more in sorrow than in anger, the story of this transfer is told (pp. 27–29). The transfer is, of course, only a part of the comprehensive measure for the revision of local government, which received the Royal Assent on March 27th, and it may be surmised that, had "asylums for the sick, insane and infirm" been imbued elsewhere with the spirit and ideals of the Metropolitan Asylums Board, no occasion would have arisen for such drastic change. In a previous report the Board made clear to the Minister of Health the value which it has set upon its work, a value which there will be few to question. Since its inauguration in 1867 the Board has enlisted the services of men and women who have devoted themselves to the work of providing, maintaining, and extending where necessary the public hospitals required by London for infectious diseases and tuberculosis, mental hospitals, ambulance and transport services, a training-ship, and other lesser services. The whole of the debt of nearly £7,000,000, raised to meet capital expenditure on the erection, acquisition, and equipment of these hospitals has been paid off, with the exception of a sum of about £300,000, representing expenditure on grant-aided services of which the Government is responsible for one-half. The Board now has under its control 25,000 hospital beds, and in times of pressure employs a staff of 10,000 persons. Its duties have steadily increased, and only last year Parliament imposed fresh responsibilities in connexion with the Metropolitan Common Poor Fund. It has been especially galling to the group of 73 members—33 elected by metropolitan boards of guardians and 18 nominated by the Ministry of Health—that they are now to be superseded by virtue of a guillotine resolution which provided no opportunity in the House of Commons for the discussion of the provisions of the Bill as they related to London, the whole of these being passed en bloc in a few minutes, so that no reference was possible in the House to the work of the Board. In other years we have taken the opportunity afforded by the annual report to call attention to one or other of the far-reaching avenues of reparative and restorative work for which the Board is responsible. The present report is the largest which has yet been issued, and after the usual summaries — administrative, general, medical— nearly 200 pages are allotted to a series of papers contributed by medical officers of the infectious hospitals, mental hospitals, tuberculosis, sick children, and dental services. To some of these we shall recur. Had the Board always presented its report in a form so attractive and well illustrated as the present, its work would have been even more widely known among the rank and file of the medical profession than it is at present. With one aspect of the work we have kept our readers closely in touch for long past, by recording the weekly bulletin of cases in the infectious hospitals. Many developments may be deduced from a careful study of this list—the increasing hospital care of measles and whooping-cough, the allotment of more than a hundred beds for the study of the results of encephalitis lethargica, the provision of beds for mothers to accompany their infants with ophthalmia neonatorum, the segregation of cases of puerperal fever for concerted study—to name but a few of the directions in which the work of the Board has led the rest of the country in the effective treatment of infectious disease.

REPRESENTATIVE MEETING OF THE B.M.A.

Manchester was much impressed, if a little mystified, by the proceedings of the Representative Body of the British Medical Association which concluded four strenuous days' business there last week. The newspapers were astonished to find that delegates working daily from 9.30 A.M. till 6.30 P.M. could easily be reconciled to the prospect of a further evening session, but this, of course, will not surprise those who know their medical profession from the inside. What was far more remarkable was the spirit in which the representatives tackled the programme set before them—a programme making continuous demands on altruism as well as understanding, neither of which was lacking. Dr. E. R. Fothergill had some justification when he described the meeting as epoch-making, for it included far-reaching decisions on the working of voluntary hospitals, the future relations of public and private medical service, and the practice of midwifery. In all these matters the profession has a hard task to keep up with the march of events which are largely beyond its control, but the schemes proposed and approved at Manchester are at the very least a laudable attempt to divert progress into paths which lead in an approved direction. Some idea of their nature and their reception may be gained from the brief report of the meeting which we conclude on another page of this issue.

PELVIC IRRADIATION IN THE PREGNANT WOMAN.

THE use of radium and X rays in gynæcology is increasing every year. It is therefore becoming more and more important to know what effect, if any, irradiation exerts upon the ovary and the embryo, and whether it is likely to prejudice the health of subsequent children. The question is difficult to investigate, for it is almost impossible to assess the numerous other factors capable of causing ill-health or defect in the offspring. Very little is known of the effects of heredity and environment upon the mother and the unborn child, or the extent to which disease in the mother, either local or general, may influence the fœtus. This is particularly important since the pelvis is only irradiated for some kind of pathological condition. All the defects of structure and function that have been observed in the children of irradiated women have also been observed in the children of others, and no condition has so far been recognised as pathognomonic of irradiation. It is nevertheless possible to draw certain general conclusions from a careful study of a series of cases. Dr. Douglas P. Murphy, of the University of Pennsylvania, has recently published an analysis of 320 pregnancies from the literature,[1] and of another 283 of which data were supplied by a number of radiologists and gynæcologists in answer to a questionaire.[2] The 320 cases in the literature included 53 women who had undergone irradiation after conception; 44 of them carried their children to term; 27 of the children presented some disturbance of health or defect in development during the period over which they were observed. Out of 198 full-term pregnancies which followed preconception irradiation, only 10, or 5 per cent. of the children were not perfectly healthy when under observation. Although no account is taken of other detrimental factors, it appears, as would have been anticipated, that irradiation is much more likely to prejudice the health of the child if performed after conception than if performed before. The children of the women who were treated after conception presented, on the whole, the more serious lesions.

---

[1] From the Office of the Board, Victoria Embankment, London, E.C. 5s.

[1] Surgery, Gynecology, and Obstetrics, 1928, xlvii., 201.

[2] Ibid., June, 1929, p. 766.

The material provided by the questionaire was, of course, much more fully documented. It did not appear that irradiation before pregnancy increased the probability of abortion. The abortion rate was 21 per cent. only, compared with the 33 per cent. suggested by various statistics as the rate for the population at large. In the group irradiated during pregnancy the rate was, however, 43·3 per cent. Of the 53 women who were irradiated when pregnant, 23 aborted while 12 of the remainder bore children who were classified as unhealthy according to the definition laid down for the purposes of the investigation. The children suffered from under-weight at birth, microcephaly, hydrocephaly, blindness, Mongolian idiocy and other gross defects of structure and function, mostly involving the central nervous system. Dr. Murphy considers that most of these disturbances may therefore be fairly attributed to the irradiation. His supposition is supported by animal experiments.[3] He regards the damage as due, perhaps, entirely to the direct irradiation of the embryo, and hardly at all to the effect of the rays upon the internal secretion of the ovaries. The unhealthy children born by the 230 women who had received irradiation before conception only numbered 15 per cent. of the total. Many of their disturbances were not serious, and none of the children showed microcephaly; moreover, all the lesions were of kinds which also appear among the children of mothers who have not been irradiated. The infantile mortality-rate was lower among the children in this group under investigation than among the general population. The conclusions which Dr. Murphy suggests are, first, that no pregnant woman should receive pelvic irradiation if the child is to be allowed to go to term, for according to his figures, there is risk that it will suffer from a serious defect; secondly, that, before a woman is irradiated, it should be definitely ascertained that she is not pregnant.

SYNTHETIC PERFUMES.

To throw a perfume on the violet, is, we learn on high poetic authority, to be guilty of ridiculous excess; but we have, it seems, approached that absurdity. In *Science Progress* for July, Mr. H. Stanley Redgrove discusses the present state of synthetic perfumery. The general conclusion we may draw from his article is that nature may be imitated very closely but that in most cases delicate noses will prefer her products to those produced in the laboratory, although these have their uses. Pure substances are rarely found in nature. So far as the organisms which yield perfumes are concerned, their main rôle is not to produce pure chemicals, but to carry on their own life and to continue it in their progeny. The odoriferous substances which they secrete are incidental to this and in most cases the odour which has caused them to be esteemed is due not only to a main product but to others associated with it. In the course of investigations on organic chemistry many odoriferous products have been separated, some identical with, others only smelling like the main constituents of natural perfume. The least attractive example of a substitute perfume is the use, now confined (and even then with danger) to cleansing and polishing preparations, of nitrobenzene for bitter almonds, of which the odoriferous principle is benzaldehyde. A more subtle case of partial identity quoted by Mr. Redgrove is that of jasmine. The natural perfume consists mainly of benzyl acetate, an easily synthesised substance, but not a very satisfactory substitute alone, as otto of jasmine contains also benzyl alcohol, linalol, linalyl acetate, methyl anthranilate, indole, and a ketonic body jasmone. Not all of these substances are pleasant smelling alone and in quantity. Many artificial "musks" have been used, since, in 1888, Baur accidentally discovered one. The best seems to be trinitrobutylmetacresol-methylether, and other nitro bodies are used. Musk itself appears to be a methyl cyclopenta-decanone, containing neither nitro group nor indeed nitrogen in any form. Synthetic vanillin appears satisfactorily to replace the product of the bean. Ionone is used now in most preparations of "violets." The main use of synthetic perfumes seems to be when blended with the more complex products of nature. Possibly a more determined effort in the direction of better culture of perfume yielding plants might enable the natural products to hold their own. While the industry is not exactly of fundamental importance to medicine, there are occasions on which the injunction *cura jucunde* requires perfumes.

CLINICAL TRAINING AT THE SYDNEY MEDICAL SCHOOL.

THOUGH there is a close association in this country between the medical schools and the hospitals to which they are attached the hospitals were mostly incorporated long before they were used as training places for students, and moreover in very large centres not one but many hospitals are needed to give the clinical facilities required for the education of one year's batch of university students. The election of university professors who are to undertake hospital duties is usually made by a joint committee consisting of representatives of the hospital and of the university, assisted by experts, but the ordinary staff appointments are generally made independently of the university, which is then invited to recognise the person appointed as an official teacher. This custom has not led to friction, though in the early years of a medical school the attempts to impose academic ideas on an institution already staffed have not always met with success. According to our Australian correspondent the conditions in which the students of the Sydney Medical School receive their clinical training are ideal, for not only is the Royal Prince Alfred Hospital, Sydney, one of the most progressive in Australia, but the Act of incorporation provides that the Senate of the University of Sydney controls the conditions under which the medical students receive their training. The result is that all the professors and lecturers *of the University medical school* are members of the staff of the hospital and all medical appointments to the hospital are made by a conjoint board consisting of the members of the University Senate, together with the directors of the hospital. Much of the present-day efficiency of the hospital is due to the sound foundations laid early in this century by the late Sir Thomas Anderson Stuart, the professor of physiology, and who was Dean of the Faculty of Medicine at the University for nearly 40 years. The board of directors of the hospital consists of ten representatives of the subscribers and governors of the hospital, ten representatives of the Government, and two ex-officio members of the University Senate, including the Chancellor and Dean of the Faculty of Medicine. There is no specific provision for a representative of the medical profession, other than the Dean *of the Faculty of Medicine, but the board has always* endeavoured to secure the election or appointment of men who represented the branches of the medical profession necessary to the efficient administration of the hospital. Under the by-laws of the hospital the honorary medical staff form a medical board, to which is referred any subject of medical importance for opinion and report. Arrangements are made periodically for the members of the permanent administrative staff of the hospital to visit Great Britain and the United States of America in order to maintain the hospital in accordance with modern developments. The specialties appear to be particularly well served. The professor of psychiatry (Dr. R. W. Dawson) and his assistants now carry out their work as part of the daily routine of the hospital. The attendance at the venereal diseases clinic, first established in 1917, has latterly become so great that it has been found necessary to limit the number of patients on any particular day. The department of urology was developed as a result of the generosity of Dr. Gordon Craig, who contributed £20,000 towards the establishment of an urological department at the university, while the committee controlling the £140,000 collected for a cancer research institute in connexion with the University of Sydney and the supply of radium made available by the Commonwealth Government has provided facilities for colloidal lead treatment at the hospital and has also installed a deep X ray therapy plant. Every cancer patient is reviewed by a conference of experts, and a decision is made whether operative surgery, radium, or deep X ray therapy or lead will be utilised. Since the establishment of the clinic there has been a marked influx of patients from New South Wales and the adjoining States. The students should also benefit from the establishment of a social service department, since they are apt to neglect during their hospital years those problems of environment and economic condition, the adjustment of which forms such a large part of their duties in private practice.

MAN AS A CARNIVORE.

It is widely believed by medical men that the consumption of large quantities of meat causes a strain on the cardiovascular and excretory systems which may be at least partly responsible for the production of arterio-sclerosis and nephritis. Moreover, a section of the profession is at the present time engaged in preaching the doctrine that meat is a dangerous form of food for human consumption on account of the risk of auto-intoxication following the absorption of putrefactive products formed from it in the large intestine. Neither of these beliefs or theories rests on any very solid foundation of established evidence, though it is possible that they are of real practical value to the clinician as a guiding principle. Any direct evidence that promises to shed even a gleam of light on the vexed problem of the harmful or beneficial effects of meat diets on mankind will always be welcome. An experiment has been recently carried out in the United States to test, as thoroughly as modern clinical and laboratory investigations will allow it to be done, the effect on man of an exclusive meat diet lasting for one year. The subjects of the experiment were the arctic explorer Stefansson (who had previously lived in the arctic regions for seven years on a similar diet) and his colleague Andersen. The exhaustive metabolic, bacteriological, and chemical investigations carried out during the year have not yet been reported in full, but a brief summary of some of the main results has been published by Dr. C. W. Lieb,[1] who took part in the work. No decrease in physical or mental vigour was observed either subjectively or objectively in either of the men, although sedentary lives were led by both. They endured the hot weather of a New York summer just as well as in former years, and at the end of the test period had a very good colour. Andersen noted that his hair stopped falling out shortly after the meat diet was started. Stefansson maintained a blood pressure of 105 systolic and 70 diastolic throughout the whole period, in spite of the fact that he had lived on an exclusive meat diet for seven years before the present test was begun. Andersen's blood pressure was 140 systolic and 80 diastolic at the beginning of the test, and 120 systolic and 80 diastolic at the end of the year. The average protein intake was not really excessive, amounting to 100 to 140 grammes a day. The bulk of the diet in each case was composed of fat. Most of the meat eaten consisted of boiled or stewed cold storage meat. Stefansson occasionally took eggs when he could not get meat; Andersen took no food but meat the whole time. In spite of the fact that this diet contained but very small amounts of calcium, no evidence was obtained by radiography that there had been any absorption of calcium from the long bones. At no time were there any signs in either subject of disturbance of the renal functions, and chemical analyses of the blood revealed no significant alterations apart from a temporary lipæmia after very large amounts of fat had been eaten. In the case of Andersen, a sugar-tolerance test carried out at the end of the meat-eating period produced a typical diabetic curve. It was noted that the stools of both subjects remained inoffensive, very few putrefactive spore-bearing organisms ever being found. The intestinal flora were in both cases simplified as regards both types and total numbers of bacteria. For the first few days of the test period Stefansson was given nothing but lean meat, and he predicted that he would soon feel ill. After two days he developed nausea and diarrhœa with lethargy and general weakness. The addition to his diet of suitable quantities of fat was followed in two days by complete recovery, and for the remainder of the year no further trouble of the kind occurred. At the end of his test period Andersen had an attack of lobar pneumonia. He made an uninterrupted recovery, and it was noticed that he showed few of the toxic symptoms of other patients in the hospital with the same type II. pneumonia. While the results of these observations are not intended to be regarded as a piece of propaganda in favour of the consumption of large quantities of butcher's meat, they are of very great interest as a demonstration of the apparent harmlessness of a meat diet to healthy white men living in a temperate climate.

A CASE OF GENERALISED BLASTOMYCOSIS.

Generalised blastomycosis is not common, and a case from the clinic of Prof. Kerl, in Vienna, recently demonstrated by Dr. E. Urbach, presents unusual features. A patient, aged 30 years, who has been under observation at the clinic for ten months, gave the history that two years ago a swelling appeared on his gums, with ulcers, and that this was followed, after six months, by swellings on the thigh, the abdomen, the neck, and face. Surgical treatment was tried, as well as X rays applied to the gums. When the patient was seen first by Dr. Urbach, a thin, purulent secretion was oozing from the lanced tumours on the neck, thigh, and abdomen. Syphilis was excluded, and all examinations of the blood, sputum, and cerebro-spinal fluid gave negative results. A mycotic disease was suspected, and microscopic examination showed the presence of a yeast in pure culture in all secretions; the yeast was found also in sections of the swellings included in giant cells. The patient gave a distinct allergic reaction on intracutaneous injection of blastomycin, and the organism was lethal to experimental animals (mice and rats). The patient suffered from chronic bronchitis. Yeast fungi were found in the sputum and cultivated, both from the urine and from the cerebro-spinal fluid. Treatment of the generalised infection with autogenous vaccine, with X rays, with intravenous injections of iodine, in large doses, had some temporary effect, but the patient soon relapsed. Recently he has had a high temperature, with rapid extension of the disease in the mucous membranes. The meninges are now affected, and the prognosis is regarded as bad. The newly instituted laboratory for mycotic diseases, attached to the Vienna dermatological clinic, has lately been able to establish the mycotic origin of many rare affections of the skin, and of certain cases of chronic bronchitis and bronchiectasis. It is possible that the yeasts are responsible when "oidium albicans" is frequent in the mouth, the œsophagus can easily be affected. Hitherto, blastomycosis has not often been reported in Austria, but now we must be on the lookout for it.

THE CLINICAL SIGNIFICANCE OF LACTIC ACID.

RECENT research into the metabolism of carbohydrates in the human body has led clinicians to study more closely the products of this metabolism in many pathological conditions. The brilliant work of A. V. Hill and others has shown that lactic acid is an important product of normal muscular activity, being formed in the process of contraction without the intervention of oxygen. It is only in the phase of recovery after contraction that a portion of this lactic acid is in fact oxidised, whereby sufficient energy is liberated to enable re-synthesis of approximately four-fifths of that originally formed into some complex precursor body. Prof. J. J. Macleod in his exhaustive account of the physiology of glycogen, lately published in our columns,[1] could not identify such an unknown precursor with either the glycogen of muscle or its free sugar. His experiments showed that it was only when oxygen supplies failed to keep pace with demands that any significant lowering of muscle glycogen occurred, and that lactic acid continued to accumulate in muscle after death, even after all the glycogen present had disappeared. It is therefore probable that some substance is formed between glycogen and lactic acid, though the nature of such an intermediary body is at present unknown. Whatever may be the exact part played by lactic acid in muscular activity, its non-removal places the body in a condition of so-called oxygen-debt, whereby it is ensured that the over-production may be gradually compensated for by an increased oxygen-intake after the acute period of excessive formation has ended. Extreme and violent periods of exercise may thus lead to an enormous accumulation of lactic acid in the muscles and blood; on the other hand even slight exertion may similarly lead to accumulation, if the processes of oxidation and removal are themselves deficient. Increase in lactic acid may thus result from over-production or from non-removal, or from a combination of both.

The normal quantity of lactic acid in the blood is reported by various workers to lie between 9 and 30 mg. per 100 c.cm. of blood, being subject to relatively wide variations and greatly increased by muscular exercise. Its subsequent fall is effected both by the prolonged increased oxygen absorption after the exertion, when the oxygen-debt is made good, and by its excretion unaltered via the kidneys and skin. Analysis of the urine and of the jerseys worn by the players after a violent game of football have shown the relatively enormous quantities of this acid that may be excreted through these channels. In some pathological conditions it is probable that a defect in one or all of these mechanisms is at fault. In hyperthyroidism, for example, a relatively small amount of physical effort is sufficient to lead to an abnormally large oxygen-debt, and Zondek has shown that the oxygen dissociation curve of the blood in this condition resembles that found during muscular work in normal individuals; it is suggested that many cases of Graves's disease are in fact the result of abnormal metabolism in the muscles, to which the thyroid hypersecretion is secondary and compensatory. In cardiac failure the highly acid urine may contain large amounts of lactic acid, and the return to alkalinity under treatment offers a valuable and important guide to prognosis; in this case the defect is both one of impaired oxidation resulting from the limited pulmonary ventilation with partial asphyxia, and one of lessened excretion by the kidneys and skin. A maximum efficiency of lungs and circulation is associated with rapid disappearance of lactic acid from the muscles, and what is known as training is probably at least in part a process of increasing this rate of removal. It is suggested that the stiffness and cramp so frequent in the unfit after bodily activity is a result of such non-removal. Bergmann and Dresel[2] have brought evidence to show that an excess of lactic acid is a cause of the muscular exhaustion occurring in myasthenia gravis, and Arai[3] in a review of intermediary metabolism quotes the increase found after injection of adrenalin or administration of thyroid extracts. Further investigation into the relationship of lactic acid to pathological states of exhaustion will no doubt continue to throw light upon these fascinating and difficult problems.

There are, however, other significant facts in connexion with this subject. Warburg has shown the importance of lactic acid in the growth of malignant tumours, and the presence of this substance in the cancerous stomach is well known. Craven Moore and Roberts[4] have gone so far as to state that its presence in a test-meal is pathognomonic of gastric carcinoma, and according to others a part at least of this acid is produced directly by the tumour; there is, it seems, an increase in blood lactic acid in patients suffering from carcinoma whenever this is associated with metastases in the liver, and it is conceivable that traces may be excreted into the stomach though there may be no growth actually in this organ itself. It is certain that disordered hepatic function may lead to high lactic acid values in the blood, and the change in the blood after a dose of this substance has been used as a test of liver efficiency. In diabetes a marked rise of blood lactic acid occurs after the ingestion of sugar, which can be immediately reduced by the injection of insulin. Tanaka[5] and others have shown a similar occurrence in experimental lack of vitamin B, and also in beri-beri in man. Arai makes the interesting suggestion that the peripheral neuritis occurring in both may be due to an intoxication by some product of pathological metabolism. It is a suggestion that deserves further consideration.

THE STORAGE OF X RAY FILMS.

THE disaster at the Cleveland (Ohio) Clinic continues to have its repercussion in all countries where celluloid film is extensively used in medical practice. Sympathy has gone out to Dr. G. W. Crile for the unkind irony of fate which singled out a man who has done so much to relieve the suffering of humanity and who has contributed so much to the safety and comfort of patients in hospitals. Particularly distressing for him has been the widespread impression that the disaster occurred in a hospital when, as a matter of fact, it happened in a building specially contructed for diagnostic and laboratory work. Such a separated clinic building was a further attempt to protect the hospital patient confined to bed. We learn from the *Bulletin* of the Cleveland Academy of Medicine, which has analysed the pathological findings, that some of the earlier deaths were due to carbon monoxide poisoning, while other more delayed reactions resulted from nitrogen dioxide. The reaction for cyanides was questionable. In a report made by the State Department of Industrial Relations to the Governor of Ohio, the immediate cause of the disaster is described as follows:—

1. X ray films in basement storage room decomposed slowly in their cabinets because of the heat from either a leaky steam pipe in the room, or from electric light bulbs hanging on ordinary cotton insulated wires.

2. Gases generated by the decomposition seeped into the room and thence into a pipe tunnel which circles the basement and thence into pipe chases which led to all parts of the building.

3. The first explosion occurred near a switch-board in the basement when the circulating gases came in contact with cold air entering the basement through an open window.

4. The second explosion probably occurred in the walls

and pipe chases and the third explosion probably occurred between the ceiling of the fourth floor and the roof.

The investigators appointed by the U.S. Army Chemical Warfare Service have now issued their own report on the causes of the disaster. A special chamber was constructed in order that experiments might be made as nearly as possible under the same conditions as obtained in Cleveland, several tons of film being employed. It was found that ignition could be provoked without the presence of a flame by such agents as hot steam piping or an electric light bulb. Mere storage of film in an overheated room gave rise to evolution of toxic gases. While combustion in a free supply of air does not result in any large quantity of poisonous gas, in a limited supply of air, and when combustion is brought on gradually, large quantities of carbon monoxide and nitrous oxide along with higher oxides of nitrogen are produced. Chemical extinguishers were found of no avail, but large quantities of water were effective if applied in good time. The comparative safety of film made with a basis of cellulose acetate was confirmed by the American investigators. Their report concludes with the statement that a storage vault 7 by 8 by 8 ft. with a 16-in. square vent in the rear wall just below the roof, held close by a 155° F. fusible link, affords reasonably safe storage for a ton and a half of film.

Two recent brochures (Nos. 74 and 76) of "Occupation and Health," issued by the International Labour Bureau in Geneva, give in concise form some of the salient facts in the combustibility of cellulose. The decomposition of the nitro-cellulose which it contains continues, once it has been started, even in the absence of air, because its complex molecule contains sufficient oxygen to combine with the hydrogen and carbon present. In the case of detonation innocuous gases, such as nitrogen, steam, and carbon dioxide, are formed. But when the material burns in a confined space the decomposition is less complete, so that nitrous fumes, carbon monoxide, and possibly hydrocyanic acid, are given off. Once alight celluloid burns rapidly, with leaping jets of flame, attaining a temperature of 1500° to 1700° C. Unstable qualities of celluloid may decompose at about 100° C. and may even take fire with an explosion, a phenomenon which for good qualities only occurs at 150° to 170° C.; but decomposition may continue without flame, even after apparent extinction of the fire, with the generation of explosive gases which may reach distant situations and cause a fresh outbreak. Conflagrations of celluloid, or its less active decomposition without flame, cannot be damped down by ordinary methods of excluding air, by immersion in carbon dioxide or in steam, since all the elements needed for combustion are present in the material itself. One gramme of nitrocellulose film is said to set free 200 c.cm. of carbon monoxide, 150 c.cm. of oxides of nitrogen, and 5 c.cm. of hydrocyanic acid, as well as traces of acrolein and camphor. Hence a fire caused by it can only be fought by men wearing gas masks, while those who are rescued must be looked upon as possible cases of gassing, particularly by nitrous fumes, the symptoms of which, although they do not become manifest for some time, may cause death within 24 hours.

As a result of the Cleveland disaster, the Public Health Council of New York State has prohibited, after September 1st, next, the sale or distribution of cellulose-nitrate film for X ray purposes, and it is understood that New York City will take similar action. The State of Ohio has issued an elaborate set of recommendations designed to achieve the same end. Cellulose-acetate films are "strongly recommended" in place of the inflammable variety, and where the latter are in use, or in storage, it is suggested that a print should be taken for record purposes and the film destroyed. In the meantime, our own Protection Committee, as it is called, has suggested certain common-sense precautions, such as the desirability of storing X ray films in special cabinets or cupboards and so limiting the number which are lying open during reference, and especially the need for a film store, isolated and cool, in the case of institutions where large numbers of films accumulate. It was stated at the recent annual meeting of the Institution of Fire Engineers in Manchester, that certain hospitals might have on their hands as much as three or four tons of film without conforming strictly to the requirements of the celluloid regulations. It was stated at this meeting that insurance companies were conferring with hospital authorities in the matter of storage. No doubt practice varies at present, but we have been given details of one large X ray department recently built in which the films, as they are returned from the wards, are filed in steel boxes which are themselves kept in a large fire-proof crypt in the basement. Such a crypt, which is remote from steam pipes and electric wiring, may be as safe as the concrete outbuilding which would be ideal where space made it practicable. We learn from various sources that the non-flam or cellulose-acetate film has not only the drawback of expense—a serious matter when radiographic films are so large—but also that it is apt to have a yellowish tinge and to be less translucent than the nitrated film. The Protection Committee indicates the undesirability of permitting smoking or naked lights in the proximity of a film store, but it is perhaps fair to repeat that X ray film is not ignited by chance contact with a glowing cigarette end. Any general rule against smoking in an X ray department would be disregarded as an indication of childish panic rather than of considered judgment.

AUTOHÆMOTHERAPY IN SYPHILIS.

A REMARKABLE case of resistant syphilis, with an intractable Wassermann reaction, has lately been described by Beume,[1] of Hanover. The patient, who presented himself for the first time in November, 1926, with a typical chancre and a negative W.R., had two courses of treatment, each consisting of ten injections of neosalvarsan (0·45 g.), and 15 injections of bismogenol, concurrently. His third course, in May, 1928, was begun too late, and was frequently interrupted, so that his W.R., hitherto negative, became strongly positive at the end of it. His fourth course included a series of mercury inunctions and ten injections of neosalvarsan. The fifth course began in December, 1928, and entirely failed to influence the progress of a tertiary cutaneous manifestation at the scalp margin. Just after the eighth salvarsan (and twelfth bismogenol) injection, the patient had a riding accident, and was brought to hospital with a hæmatoma of the knee and ankle-joints. During his four weeks' detention there was mild fever. He said nothing to the hospital authorities about his luetic infection, but on discharge on March 12th of this year presented himself at Beume's clinic, where it was found that the cutaneous lesions had disappeared, and the W.R. had become completely negative. Beume remarks that the pyrexia, as well as the hæmorrhage, may have influenced the sequel, and raises the interesting question whether the proteins set free in the serum, or the fact of their having been previously salvarsanised, was the more important factor in bringing about a cure. He maintains that the proposal, which he has previously made, to treat Wassermann-fast cases by a combination of salvarsan, bismuth and autohæmotherapy, receives further support from this case.

---

[1] Derm. Woch., June 6th, p. 812.

SALARIES OF HEALTH OFFICERS IN U.S.A.—The New York State Department of Health states that with the increased number of full-time health officers, there is awakening a more general disposition to remunerate more fairly all health officers for their services. In a comparison recently made of cities of 100,000 population or over as to the salaries paid health officers in 1923 with the salaries paid in 1927, it was found that the average salary increased from $5000 to $6200; in cities of 50,000 to 100,000 population it increased on an average from $3404 to $4570.

The Clinical Interpretation of Aids to Diagnosis.

A Series of Special Articles contributed by Invitation.

XXXVIII.

INTERPRETATION OF THE SCHICK TEST.

THE Schick test has now become a well-established clinical aid to diagnosis; it is, therefore, important to have a clear idea of what we ask it to tell us under any given circumstances and to what extent we can rely upon the answer.

The test consists in the intradermal inoculation of a minute amount of diphtheria toxin accurately measured; in susceptible persons a characteristic red circular swelling appears. In such persons the injection of antitoxin will produce immediately passive immunity which will last about three weeks, whereas by giving prophylactically toxin rendered non-poisonous by the action of chemical and physical agents—i.e., "toxoid," with or without the addition of antitoxin, in three doses a week or more apart, active immunity of indefinite duration can be produced.

Technique of Test and Reading of Results.

The technique is simple; the prescribed dose of toxin—with English products, 0·2 c.cm., with American and continental mostly 0·1 c.cm.—is injected intradermally. It is advisable to use the special sharp rustless steel needles, much smaller than the ordinary hypodermic size, sold for the purpose; the plunger of the syringe must fit so tightly that liquid cannot readily be forced past it by any finger pressure. If the needle be held nearly parallel to the skin it is easy to inject intradermally and produce the desired small circular swelling. Even if the operator feels that he has gone too deeply, the proper reaction will probably be obtained, but it is easy to repeat the injection an inch away in the forearm. It is wise always to assign the same forearm—preferably the left—as the one for the toxin injection, and the other for the control fluid. Clear descriptions of the various reactions to be looked for are usually supplied with the various products on the market.

The *negative* reaction, when there is no local red reaction on either arm, and the *negative-and-pseudo*, with equal reactions on the two arms usually fading in a few days, indicate that the patient has a high degree of immunity against diphtheria; he is considered as "immune" against the disease.

The *positive* reaction shows a red flush from half an inch to two inches wide. This usually appears within 24 hours, but may be delayed until the second day and in unusual instances to even the third or fourth day. It is wise to make a final reading on the seventh day. The redness gradually disappears, a fine scaling may occur, and the resultant brown stain fades slowly during the next few weeks. (It is well to offer women patients the option of being tested just above the knee, for a circular brown stain on the forearm, which in patients with sensitive skins may last for some weeks, may be resented.) The right arm into which the control fluid is injected may show a red reaction, while the left arm shows a much larger and probably more intense reaction. This *positive-and-pseudo*, and the simple positive reactions indicate that the patients have either minimal or no immunity against the disease; they are "susceptible."

Clinical Use of the Test.

We may use the test (*a*) in considering whether a given patient has diphtheria, (*b*) we may ask is a given subject immune when we are attempting to control an epidemic, or (*c*) when merely seeking the susceptibles in a non-epidemic period in order to immunise them.

(*a*) If we Schick-test patients with sore-throat, we must consider the result first in its relation to treatment, secondly as a help in administration. It is true that practically every patient admitted to an isolation hospital suffering from diphtheria is Schick-positive (unless, of course, antitoxin has already been given). But for the average patient treatment should not await the application of, or result of, the Schick test. All experienced authors agree that the practitioner responsible for treating a patient complaining of a sore-throat, with some membrane present, which he thinks is probably due to diphtheria, must give antitoxin at once without awaiting the results of swab or of Schick test. The records of every large isolation hospital show that deaths and instances of prolonged convalescence with paralysis or cardiac weakness occur due to failure to give antitoxin when the patient is first seen and the suspicion of diphtheria first arises in the practitioner's mind. From the *administrative* point of view, on the other hand, the test may give great help. The injection of the Schick dose of toxin will give a correct reading even if antitoxin be given four or more hours later. In some hospitals all patients with a "mild" attack are Schick-tested and either given antitoxin four or five hours later —or the physician, guided by long experience of diphtheria, may decide that the patient requires no antitoxin. But this is not a decision for which the wise general practitioner, who has not the patient under observation from hour to hour, will ever wish to take responsibility. If a patient suspected to be suffering from diphtheria gives a negative response to the Schick test, it is very unlikely that the disease is diphtheria. To most useful medical rules there are exceptions. Rare instances are recorded in which "mild diphtheria" has been seen in patients known to be negative to the Schick test—e.g., sore-throat with a slight amount of membrane, temperature probably never reaching 100° F. and a very slight disturbance of health, with absence of complications during convalescence.

To sum up, the Schick test used with discretion may aid in treatment, but it cannot always give us decisive information that will relieve us of the duty of giving antitoxin where diphtheria is suspected; it may be of great service in deciding whether the case should be treated from the public health point of view as one of diphtheria.

(*b*) When attempting to control an epidemic in a school or institution, the test will aid us much. The method has been often described. The whole population is Schick-tested and divided into positive and negative groups. In the latter no diphtheria will occur; only amongst the positive reactors will cases appear. The two groups are swabbed in the search for "virulent carriers" amongst the negative reactors, and to detect, in the stage of incubation, any diphtheria amongst the positive reactors. (If the outbreak be a violent one, it can be stopped entirely by giving antitoxin at once to the positive reactors. Some three weeks later active immunisation may be begun.) Where possible, however, it is better to employ active rather than passive immunisation.

(*c*) When we begin to immunise a group of people as a prophylactic measure, the test is the basis of the whole procedure. With the knowledge and experience gained during the past decade by testing on the large scale, we can say whether, as a compromise, it is permissible to immunise without testing. Since most children of early school age are positive to the test, the tendency of public health authorities is to immunise all children up to the age of 6 or even 10, without preliminary Schick-testing. Some public health authorities do not test as a routine after immunisation. This saves time and money, the obvious disadvantage being that cases of diphtheria may occur amongst the inevitable small residuum of children who do not become Schick-negative after one course of any of the diphtheria prophylactics available, and this may discredit the whole procedure.

Reservations.

Error may conceivably arise from faulty technique, readings, or the conclusions drawn. Reliable "buffered" diluted toxin of sufficient stability is now available and the technique of the test is simple. The reading of the reaction can be made in the great majority of instances readily and with confidence. A pale red coloration 5 mm. in diameter is clearly a negative reaction, a violent red one of 20 to 30 mm. clearly positive. A small number of reactions may make one pause; pale reactions from about 5 to 10 mm. in diameter are difficult to read as either positive or negative; the reading on the seventh day, however, will clear up most difficulties. The wise practitioner will not, in such instances waste time. He will leave the conclusion to any expert available or will make whatever decision will be least dangerous to the individual tested. If the symptoms of the patient suggest diphtheria, but the Schick test is returned as "negative," the doctor will be well advised to conclude that a mistake has been made in the test and to be guided by his clinical observation; he will, therefore, give antitoxin. If the reaction be a "doubtful" one, he will conclude that it is really positive and will give antitoxin. In testing with a view to immunisation, or retesting after immunisation, he will give prophylactic treatment to all with "doubtful" reactions.

ROYAL ARMY MEDICAL CORPS.

The undermentioned Capts. to be Majs.: J. C. Collins (prov.), and remains secd.; W. I. FitzG. Powell, and remains secd. G. W. B. Shaw.

Lt. (on prob.) N. J. Nicholson resigns his commn.

ARMY RESERVE OF OFFICERS.

Lt.-Col. C. A. J. A. Balck Foote having attained the age limit of liability to recall ceases to belong to the Res. of Off.

TERRITORIAL ARMY.

Col. J. S. Riddell (late R.A.M.C., T.F., ret.) to be Hon. Col. R.A.M.C. units, 51st (Highland) Div., T.A.

Lt. J. Cook to be Capt.

Supernumerary for service with O.T.C.: A. J. Parer to be Lt., supern. for serv. with Med. Unit, Univ. of Lond. Contgt., Sen. Div., O.T.C.

INDIAN MEDICAL SERVICE.

Col. J. W. D. Megaw to be Maj.-Gen.

Lt.-Col. H. M. Mackenize to be Col.

Maj. G. R. Lynn to be Lt.-Col.

Capts. G. M. Moffat, L. G. Pearson, and Pirojsha Merwanji Antia to be Majs.

DEATHS IN THE SERVICES.

Surg.-Commander Devonshire Penrose Hawkes Pearson, R.N., who died on July 22nd, entered the Navy as a surgeon in 1913, and was appointed to the cruiser *Antrim*. He served in the Grand Fleet during the early part of the War. In 1916 he was nominated for special duty in the Mediterranean, and in 1918 became P.M.O. of the new cruiser *Danæ*, with the acting rank of surgeon lieut.-commander. He was confirmed in this rank in 1919, and was promoted to surg.-commander in 1925. He retired from the service last year.

Special Articles.

MODERN HOSPITALS IN SWEDEN AND DENMARK.

By H. S. SOUTTAR, F.R.C.S. Eng.,
SURGEON TO THE LONDON HOSPITAL.

It is probable that the next few years will see a general reconstruction both of our hospital system and of our hospitals themselves, more especially in the provision of a hospital service for private patients of every class. I therefore welcomed the request of my colleagues on the staff of the London Clinic and Nursing Home, a large private hospital which is at present being erected in London, to visit the clinics of Sweden and Denmark and to gather such information as might be of use to us in equipping this new hospital on the most modern lines. Our party was formed of the managing director, the architect, the domestic bursar, and myself, so that we were in a position to criticise and appreciate all we saw from every point of view.

Nothing could have exceeded the kindness with which we were everywhere received, and every possible facility was placed at our disposal. In the course of ten days we travelled nearly 3000 miles and went over 17 hospitals from the cellars to the attics. We were very greatly impressed by all that we saw and by the immense strides made in medical service throughout Scandinavia. It has become a national service in the best sense of the term, supported by the resources of the State, organised and controlled by a progressive medical profession, and quite obviously used and welcomed by the public, both as a privilege and as a right.

The position of these hospitals must be understood if their significance is to be appreciated. The organisation differs greatly from that familiar to us. Sweden is divided into a number of administrative counties and each of these is responsible for the care of its own sick. In a central town a large hospital which serves the whole county is erected and maintained by the county authorities, who have a considerable measure of autonomy. In only a few large towns, such as Stockholm itself, are these special hospitals maintained by the municipal authorities, and here also are a few independent endowed institutions, such as the Diakoniss Hospital in Stockholm.

Payment According to Accommodation.

In every one of these hospitals, even in those which correspond to our poor-law infirmaries, the patient has to pay according to accommodation. It is true that with the working class these payments are met from insurance societies, membership of which is universal, whilst the charges themselves are exceedingly moderate, varying from 3*s.* to 21*s.* a day with the accommodation. It is, however, a perfectly definite payment for services rendered, and although it is backed by the State, or in a few cases by endowment, there is quite obviously no question of charity in the transaction.

As to the accommodation provided, it is everywhere of a very high order. There is a general tendency towards the abolition of large wards and the limitation of the beds to six or eight at the most. The majority of the beds are in rooms taking one, two, or three patients, and as a result the patients have a degree of privacy impossible on the older system. This might at first appear to involve additional work for the nursing staff, but the arrangements are so convenient that this does not result. In every hospital ample provision is made for private patients, but the accommodation differs only in small refinements from that in the rest of the hospital, for, indeed, the latter can hardly be improved upon.

A Medical Director.

In all the public hospitals visited by us the professional work is under the control of a medical director, who mostly has a large degree of executive control, and a number of assistants working entirely under his authority. The system is the usual one maintaining on the Continent and differs fundamentally from that customary in this country. It cannot be denied that it leads to a degree of coördination which must be of advantage both in the progress of medical science and in the treatment of the individual. It necessarily involves, however, the concentration of all the more important work in the hands of a few individuals, and the effect of this is accentuated by the fact that practically the whole surgical work of the country, both public and private, is carried out in the hospitals. It is true that in Stockholm and Gothenburg there are large private hospitals, open to all practitioners, but, in general, surgical practice is only carried on within the walls and by the staff of the local hospital.

Spacious Buildings.

The buildings themselves give an impression of spaciousness and of coherent design which is very impressive. The Academic Hospital, at Upsala, with accommodation for 577 patients, is situated in grounds 25 acres in extent, yet the buildings are so arranged that access from one to another is easy. Even in the great County Hospital of Copenhagen, which is designed for an ultimate capacity of 1000, contact between the various departments and sections of the hospital is easily maintained by large underground tunnels. Spaciousness and accessibility have been combined with extraordinary skill.

The feeling of space is maintained by the large airy corridors upon which all the modern hospitals are based. With the use of separate rooms for the patients the pavilion system, in the ordinary form, ceased to have any advantage, so that some modification of the corridor plan is universal. The corridors have been kept clear of every encumbrance, even the doors lying flush in their walls, and to look down one of these long corridors, silent and empty, to a window in the far distance is impressive. Silence indeed is one of the most remarkable features of these hospitals, for the floors are covered with rubber or cork, the doors are hollow and packed with wool, and there are no bells. Every now and then a light appears in a little bulb over one of the doors, to indicate that a patient requires the nurse, and its silent call adds still further to the impression of quiet.

The Patients' Rooms.

The patients' rooms are of adequate size, much larger than those in many of our nursing homes, and the fittings are simple and well designed. The fact that box-spring mattresses are almost universal shows the standard of comfort supplied. Central heating is everywhere in use, and the double windows, necessitated by a Scandinavian winter, are so arranged as to allow of full ventilation without a draught. The excellence of the ventilation of all the hospitals we visited was a surprise to those of us who are familiar with Continental custom. In the private rooms hot and cold water is always laid on, and in the private Red Cross Hospital in Stockholm each room has its own lavatory attached.

The Baths.

As one would expect in Sweden and Denmark, the bath departments are constructed on a magnificent scale, and one would have to go to Bath or to Buxton to find their rival in this country. Every conceivable form of bath is supplied, and all are in constant use. It appears that rheumatism is a serious problem, and almost every hospital has a separate rheumatic section, specially supported by the State. It takes the form of a boarding-house to which patients can be sent from any part of the county served by the hospital and where they can live comfortably at very low rates, usually met by insurance, during their treatment. The whole organisation seems admirable, and it might well be adopted in this country.

X Ray Equipment: Operating Theatres.

The X ray equipment was everywhere of the highest order and few hospitals in this country could approach what appears to be an almost standard installation. The diagnostic and therapeutic departments are in every hospital entirely distinct, with entirely separate generators and equipment. The diagnostic department is generally equipped with the convenient apparatus designed by Prof. G. Forssell, and the generators have usually a capacity of 120,000 volts. In the newer hospitals Stabilivolt generators by Siemens and Halske are installed, with a capacity of 320,000 volts, for purposes of treatment. The finest of all is the equipment at the County Hospital of Copenhagen, where the new "cannon" apparatus is the last word in radiotherapy; this whole department, controlled by Dr. Leif Arnzten, stands by itself as an example of superb equipment and design.

The operating theatres are everywhere designed on a lavish scale and are arranged in self-contained suites of theatre, anaesthetic room, sterilising room, surgeons' room. One of the finest is at Västerås, where the central section of the top floor is given up entirely to theatres. A large sterilising room with completely duplicated equipment is placed between two large theatres. Behind these a very large corridor gives direct access to all three and forms an ante-room. From this opens on the other side, dressing rooms, sisters' stores, a special X ray room for pyelograms and other special work, and a writing room for the surgeons. It is true that modern theatres in this country are arranged in a similar way, but rarely with such convenience and never with so much space and light.

Unlimited Space and Light.

One accustomed to working in a hospital in London is perhaps most impressed by the unlimited space and light available. The wide airy corridors, the large balconies on to which beds can so easily be wheeled, the ample space provided for the operating suites, and the obvious consideration for the comfort and convenience of all those who have to work in the hospitals, are evidence of sound organisation and thorough efficiency.

In the hope that it may be of assistance to those who are anxious to see for themselves the hospitals of Sweden and Denmark, a list is appended of those which appeared best adapted to the requirements of this country.

—	Beds.	—
STOCKHOLM. Sophiahemmet ..	95	Private hospital with training school for nurses.
Red Cross Hospital	60	Private hospital.
UPSALA. University Hospital	577	Director: Prof. Nystrom; Asst. Director: Dr. Westerborn.
VÄSTERÅS. Central Lazarett ..	235	Director: Dr. Norrlin; Asst. Director: Dr. Berner.
NORRKÖPING. Lazarett ..	350	Director: Dr. Bager.
COPENHAGEN. Bispebjerg Municipal Hospital	800*	Surgical Director: Dr. Wessen.
Kobenhavns Amts Sygehus (county hospital)	300†	Medical Director: Dr. Jorgensen; Surgical Director: Dr. Helsted; Secretary: Inspector Knud Warming.

* To be increased to 1800. † To be increased to 1000.

It must not be imagined that these hospitals are a new departure in policy; they are rather part of a steady evolution, the evidence of a very remarkable appreciation in Sweden and Denmark of the value of modern medicine and surgery, and of a determination to give them every material assistance that is possible. They are State hospitals in the sense that they are built, equipped, and subsidised by the public authorities, but it is very evident that they are no product of a bureaucratic system but of a wholehearted coöperation between the medical profession and the State. In the very best sense of the word they are National hospitals, and we who visited them are convinced that only on the basis of National funds can such services be supplied.

The Defects of the Voluntary System.

Voluntary effort has done magnificent work for the hospitals of this country, but the problem has entirely changed and has passed beyond its powers. On the one hand, owing to the extraordinary advances in medicine and surgery during the last 20 years, it is impossible for private charity to cope with their demands. On the other hand, the sick poor for whom our hospitals were founded have disappeared, and in their place a class is demanding, and in my opinion rightly demanding, admission to our hospitals, who would resent the suggestion that they are the objects of charity. The care of the health of the nation is now recognised to be a function of the State, and it is impossible to dissociate our health from our hospitals. Unless our hospitals are maintained at the highest level of modern efficiency, we are bound as a nation to fall behind.

Far from our hospitals being as they once were the envy of other nations, the great majority are years behind the times, and lack of funds compels the hospitals of our metropolis to carry on their work in the heart of London with an equipment and in surroundings which would not be tolerated in a small provincial town in Sweden. Most of them are in financial difficulties and some are virtually bankrupt, so that it is inconceivable that they should be able to bring themselves up to date, whilst their mere maintenance makes quite unfair demands upon those who have hitherto so generously borne the responsibility upon their shoulders. They have made a gallant fight against social and economic changes which have altered entirely the clientèle which they serve and removed the old sources of their income, whilst they are faced with financial demands such as voluntary effort can never be expected to meet.

The Future.

Is it not time that we recognised these facts and faced boldly a complete reconstruction of our whole hospital system? All of us who have grown up under the old system, where the charity of our nurses, of our doctors, and of the public worked hand in hand to relieve suffering and to help the poor, will view its departure with regret. Yet I feel confident that the future will hold far greater opportunities than the past, and I have returned from my visit to Sweden and Denmark not so much depressed by the backward condition of our hospitals as stimulated by the prospect of the possibilities which lie before us. For I am convinced that we shall set our house in order and regain our lead.

In conclusion, I can only express our gratitude to our friends who placed at our disposal so generously their time and the resources of their hospitals, and most of all to Prof. Viggo Christiansen, of Copenhagen, and Dr. John Hellström, of Stockholm, who organised our visit and to whom we owe its success.

REBUILDING OF MIDDLESEX HOSPITAL.—At a meeting of the Court of Governors last week Prince Arthur of Connaught, the Chairman, gave an account of the progress and finance of the scheme of rebuilding. The work in hand and provided for includes the new west wing, a new nurses' home (an anonymous gift), a new residents' house, a block for paying patients (the gift of Lord Woolavington), an annexe ready to be converted into an out-patient department, and a great central power house, in addition to Mr. S. A. Courtauld's gift of the Institute of Biochemistry. The amount still required to complete the building is £380,000 and there is a gap of about £16,000 a year between receipts and expenditure. A sum of £15,000 is required immediately on current account.

MEDICINE AND THE LAW.

Colonel Kynaston and the General Medical Council.

THE failure of Lieut.-Colonel J. W. Kynaston's action against the General Medical Council blocks one possible avenue by which a medical practitioner, aggrieved at the removal of his name from the Register in consequence of charges of unprofessional conduct, might conceivably succeed in reopening the merits of the disciplinary issue. Nothing is more certain in the legal view of such issues than the fact that, if the General Medical Council has properly conducted its inquiry into the conduct of a practitioner charged under Section 29 of the Medical Act with "infamous conduct in any professional respect," the law courts will flatly refuse to interfere with the Council's finding or to rehear the matter by way of appeal. Colonel Kynaston, therefore, could not possibly succeed in his recent attempt to have the record of his removal deleted unless he could show that the Council had acted without jurisdiction, or with bias, or in some other fashion contrary to natural justice. His attempt was based on three grounds. One of them was a definite allegation of bias. The conduct in respect of which his name was removed from the Register some seven years ago was, he contended, in part a criticism of Sir George Newman's administration as Chief Medical Officer of the Ministry of Health: Sir George Newman was, he complained, a member of the committee which decided the disciplinary issue; *ergo*, the tribunal was biased and prejudiced. When a party enters upon litigation his legal advisers will, of course, expect him to use every possible weapon; Colonel Kynaston, in making what the Lord Chief Justice called a "faint suggestion" of bias in the circumstances stated, may have been relying rather upon a technical than a substantial foundation. The King's Bench Division made short work of his allegation. Lord Hewart remarked caustically that there were only two answers to it: firstly, that there was not a tittle of evidence of bias, and secondly, that Sir George Newman did not take part in the decision.

The other two grounds of Colonel Kynaston's application were less invidious. He maintained that the book and letters in respect of which he was accused of unprofessional conduct amounted to the adoption and advocacy of a theory of medicine and surgery, and was, therefore, privileged under Section 28 of the Act; disciplinary action taken in these circumstances was, he argued, illegal. Further, he claimed that he had applied to have his name removed at his own request before the charges formulated against him were tried; the examination of the charges thereafter was, he contended, improper. On this latter point the judges of the King's Bench Division made it clear that a practitioner, if minded to do acts which would clearly invite disciplinary proceedings, cannot claim to have his name removed from the Register, and afterwards, when those acts have been completed, claim to have his name restored again. Mr. Justice Avory pointed out that the statutory declaration required from a practitioner who seeks to have his name removed from the Register at his own request contains a statement that he is not aware of any proceedings, or of any reason for proceedings, for the removal of his name penally. Mr. Justice Branson remarked that even on such voluntary application the Council is to remove the name "if it thinks fit," so that there still remains a discretionary power in the Council. Looked at generally, as the Lord Chief Justice observed, no small part of Colonel Kynaston's case was an invitation to the King's Bench Division to review the decision reached by the Council seven years ago. "It is well settled," said Lord Hewart, "that the Court has no such power: the Council did the very thing which the law empowers them to do." The matter, he added, which was seven years old, had been stirred, not because any human being could seriously consider that there was any ground for undoing what the Council had done, but because Colonel Kynaston had been summoned for another offence under the Medical Act, and it was desired to add a make-weight to the defence in those proceedings.

The Police-court Proceedings: Colonel Kynaston's Appeal.

In those police-court proceedings[1] to which Lord Hewart was alluding, a fresh step was taken by Col. Kynaston on July 15th, when he made an application at Marlborough-street police-court with a view to appealing against Mr. Cancellor's decision dismissing summonses against him under the Probation of Offenders Act.

It may seem strange that there should be an appeal where there has been no conviction, but the Criminal Justice Act of 1925 (Section 7, as amended in 1926) allows a person in whose case any order under the Probation of Offenders Act has been made by a court of summary jurisdiction to appeal to quarter sessions as if he had been convicted, provided that he did not plead guilty or admit the truth of the information at the original trial. Mr. Cancellor, it will be remembered, dismissed outright the summons charging the defendant with having wilfully and falsely pretended to be a doctor of medicine. The second summons, charging him with wilfully and falsely using the title "M.R.C.S. Eng.," Mr. Cancellor found proved; Col. Kynaston must, he thought, have known that the use of those letters would lead readers to believe that he was still a member of that distinguished body. The magistrate, however, refused to register a conviction on this latter charge because of the following extenuating circumstances: first, Col. Kynaston had no opportunity of arguing his case before the Royal College of Surgeons; secondly, a somewhat similar summons was withdrawn a year or two ago—a fact which might have lulled him into an erroneous sense of security from further proceedings; thirdly, Col. Kynaston had done distinguished work both in his military service and in his civilian practice afterwards. As, however, the magistrate accompanied the dismissal of the summonses with a serious warning of future penalties if the defendant persisted in publishing the advertisement, it is natural that Col. Kynaston should wish to reopen the decision.

"Wilfully and Falsely."

It was made clear in the previous proceedings against Col. Kynaston that there was no suggestion of fraud. In proceedings under Section 40 of the Medical Act of 1858 it is an important element of the charge that the accused should have "wilfully and falsely" pretended to be, or should have "wilfully and falsely" taken or used a medical title or any name, title, addition or description implying that he is registered or recognised by law as a medical practitioner. The principal leading cases on the meaning of "wilfully and falsely" have been those in which American "correspondence" degrees were in question—an abuse which has now largely ceased. In Andrews *v.* Styrap (1872), Thomas Andrews had used the letters "M.D." after no more elaborate qualification than the purchase (without going to America, studying or passing any examinations for such degree) of a diploma as a doctor of medicine from the University of Philadelphia. Baron Martin, when the case came up to the Exchequer Division, remarked, "this is no diploma at all, it is a mere pretence." The magistrates, he said, were right to convict: "there was ample evidence that the appellant *wilfully* (for he did it on purpose) and *falsely* (because he pretended thereby to be on an equal footing with any regularly bred and registered physician or M.D. in England) took, assumed, and used the title of 'M.D.' under a diploma obtained by him from an American University without any course of previous study or any examination, but simply on the payment of a sum of money, and which diploma therefore he must have known to be in fact utterly worthless and valueless as an indication of the possessor's merit, learning, and skill as a physician or as giving him any of the privileges of a registered medical man." On the other hand, in Carpenter *v.* Hamilton (1877) the accused had held himself out to be "Dr. John Hamilton, Doctor of Medicine of the Metropolitan Medical College of New York," and it was never proved that he did not possess this qualification. "How is it possible," asked Baron Cleasby in the Exchequer Division, "to make out a charge of falsely pretending to be something, when the only evidence is that the man pretends to be what he really is?" Baron Martin's exposition of "wilfully and falsely" in Andrews *v.* Styrap is still relied upon. If it is applied to Col. Kynaston's case, it may be easy to say that the defendant used the letters "M.R.C.S. Eng." wilfully "because he did it on purpose"; it is not so easy to say that he did it "falsely" because his original possession of the diploma was justly founded on established grounds of "merit, learning, and skill." The cancellation of the diploma was not due to any reflection upon his "learning and skill." The law may be clearer when Col. Kynaston's litigation is complete.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

Murder by Strophanthin.

A medical man, Dr. X., was recently tried for murder in Bonn, in curious circumstances. He had an entanglement with a woman, Mrs. Y., who had been a nurse, which was inconvenient in view of his desire to marry someone else. One evening when Mrs. Y. was in the doctor's house, she was heard to cry out that she had been poisoned, and that she wished to be examined at once at the university hospital. Dr. X. himself carried her to the hospital where he declared to a medical officer that she was very hysterical, but that as she complained of heavy pains in the rectum, a rectal wash-out might be indicated. The woman continued to cry that something had been introduced into her rectum, and as she was very excited, she was at once taken to the clinic for nervous diseases, where she died an hour later. At the autopsy, strophanthin was found in the rectum, whereupon Dr. X., whose behaviour had aroused suspicion, was arrested, and tried for murder. At the trial a chemist gave evidence that some days before Dr. X. had presented a prescription for strophanthin in crystalline form. On being informed that strophanthin was in stock only in solution, he had induced the chemist to procure it in crystalline form. In handing over the drug to the defendant, the chemist warned him that it was a strong poison. Defendant replied that he wished to use it for cauterising the nose of a patient. Medical witnesses gave contradictory evidence; a professor of pharmacology stated that though strophanthin might be used for that purpose it was an uncommon technique. A professor of rhinology declared that he had never heard of strophanthin being used for cauterisation. Defendant said that the woman had complained of pain in the rectum, and that he had therefore performed a rectal examination. Being very hysterical she might have taken the drug from his table and introduced it into the rectum herself for suicidal purposes. He admitted, however, that the dead woman had been his mistress. After a trial lasting four days, which caused a great sensation throughout Germany, Dr. X. was sentenced to death for murder. The case is unique, since murder by strophanthin has never before been recorded. The plea of insanity made by the defendant's counsel was not accepted by the Court.

Legal State of Pharmacies.

Dr. Lustig, a government medical officer, recently read a paper before the Berlin Society for Public Health, on the legal position of pharmacies, which is very variable. Certain pharmacies possess rights connected with certain premises, which may date back some railways and that of the old streams. In order, however, to regard the railways as a third factor producing an indirect association between rats and acute rheumatism, it is necessary to assume that dampness and acute rheumatism are related. The report mentions, however, another fact which suggests that rats and rheumatism are related, whether causally or not. Both occur most frequently in defective houses, where rats can gnaw their way into the spaces below the floor-boards in the basement and ground-floors. Rats, moreover, are attracted by untidy yards and kitchens. As we remarked in our previous comment, the work of other investigators has shown that acute rheumatism is very common in needy households, but is rare among the very poor. Social workers know well that the inhabitants of the class of premises which are infested by rats tend to be untidy and wasteful in their manner of life, while persons on the verge of destitution, to whom every scrap of food is important will presumably offer rats little or no hospitality. The Kensington report also shows a close correspondence between acute rheumatism and density of population, another factor favourable to infestation by rats.

---

[1] See THE LANCET, July 13th, p. 95.

These data prove nothing conclusively, but suggest a great deal, and must provoke other workers to make investigations on the same lines. The next report from Kensington, which will show whether the correspondence is confirmed or diminished when the number of notified cases is larger will be awaited with interest.

Public Health Services.

THE HEALTH OF LONDON IN 1928.

Statistics.

Estimated population. 4,458,200. Birth-rate, 16·2. Death-rates per 1000 of the population, all causes, 12·1; pulmonary tuberculosis, 0·89; non-pulmonary tuberculosis, 0·14; cancer, 1·52; pneumonia, 0·93; bronchitis 0·59. Rates per 1000 births: Infant mortality, 67; maternal from childbirth, 3·59.

AMONG the 28 metropolitan boroughs the following are some of the highest and lowest rates. The three highest birth-rates were: Shoreditch 20·7, Finsbury 20·4, Poplar 19·9; the three lowest Westminster 10·4, Hampstead 11·6, Holborn 12·0. The three lowest death-rates were: Lewisham 10·0, Wandsworth 10·9, Woolwich 11·0; the three highest were Shoreditch 13·6, Holborn and Chelsea each 13·5. The three lowest infant mortality-rates were: Chelsea 48, Wandsworth and Woolwich each 50; the three highest were Paddington and Kensington each 85, Finsbury 84. The three lowest phthisis rates were: Hampstead 0·45, Kensington 0·60, and Wandsworth 0·71; the three highest were Finsbury 1·29, Bermondsey 1·28, Shoreditch 1·19. The three lowest rates for maternal mortality from childbirth per 1000 births were: Bethnal Green 1·40, Stepney 2·00, Holborn 2·11; the highest were Westminster 13·06, St. Marylebone 6·82, Stoke Newington 6·45.

Dr. F. N. Kay Menzies points out that, as would be expected in an ageing population, there was an increase in recorded deaths from diseases of the heart and circulatory system and from old age. Fatal street accidents caused 747 deaths, as compared with 669 in 1927, but these fatal accidents to children caused the same number of deaths in both years—viz., 149. The increase in infant mortality from 59 to 67 was largely due to diarrhœa and measles. The death-rate among children under two years from diarrhœa and enteritis was 10·32 per 1000 births, as compared with 7·59 in 1927. During 1928 London was attacked by small-pox of the mild type. The infection was brought to the south of England by a tramp who reached a Sussex casual ward in a collapsed condition in December, 1927, but the nature of his illness was not suspected until secondary cases occurred a fortnight later, the diagnosis being then confirmed by the council's small-pox consultant. By this time vagrants infected in this casual ward had spread the disease over the countryside. In all there were 285 confirmed cases, with one death in Southwark. The London experience showed that vaccination protects equally against the mild and the more virulent forms of small-pox.

The deaths from measles totalled 1358, the highest number since 1922. Measles was prevalent in London both in 1917 and 1918, and since then has been epidemic in alternate years. It is due again next winter and likely to be accompanied by a prevalence of whooping-cough above the average.

Maternal Mortality.

Dr. Menzies devotes much consideration to the statistics relating to maternal mortality and puerperal fever. In the first place he points out that the fertility of married women of the "better" class is lower than that of the poorer class owing to the higher age at marriage, but that only a relatively small proportion of the difference in the extremes of social class is attributable to difference in the actual age of the mothers. In the census for 1911 the social grouping is faulty, but appears to indicate that the fertility in the lower groups is one and a half times that of the higher groups. Dr. Menzies, on the other hand, gives figures which indicate that the fertility of the mothers of elementary school-children is 3·6 times that of other mothers in the County of London. He stresses the point that much more accurate data for social grouping should be obtained in the forthcoming census of 1931. The metropolitan boroughs which had a low maternal mortality in 1920-27 were Finsbury, Shoreditch, Greenwich, and Stepney, and in all of them the proportion of illegitimate births was low, whilst in Chelsea, St. Marylebone, Westminster, and Stoke Newington, where the highest maternal mortality occurred, the percentage of illegitimate births was generally high. During 1901 to 1910 there was a considerable decrease in maternal mortality attributable probably to the provision of better-trained midwives. Since this period the decline has been much less. In order to define and direct measures for the improvement of maternal health is is essential that greater attention should be given to records bearing upon maternal conditions, and one detail needed is a record of the age of the mother when each birth is registered. This point was especially emphasised by Dr. T. H. C. Stevenson in his evidence before the National Birth-rate Commission in December, 1914, but no action has yet been taken. Dr. Menzies gives figures to show that maternal risk in childbirth is lowest at ages under 25 years and increases rapidly with age after the thirtieth year, and that in such a comparison allowance has to be made for the double risk at a first confinement.

Another point brought out by the figures is the inverse relation of maternal mortality and fertility. A woman marrying at 18 and having three children before the age of 25 has a death risk of 2·07 per 1000 children born, whilst a woman marrying at 33 and having three children before the age of 40 has a death risk of 5·86 per 1000 births. Figures from New South Wales show that the maternal mortality-rate would be at a minimum if each married woman had four children. After the fourth child the risk increases. Other points are that a smaller family increases the maternal mortality by exaggerating the effect of first confinements and that the decrease in childbirth mortality among women under 30 is greater than the decrease in other causes of death, which recalls the fact that there has been lately noted in London an increased mortality among single women from phthisis.

Puerperal Sepsis.

Dr. Menzies questions the deductions made in the Aberdeen report on puerperal sepsis, issued by the

Scottish Board of Health in 1928, and gives his reasons for so doing. He goes on to produce evidence that the resistance to puerperal fever diminishes markedly with age, and to show fluctuations in the annual puerperal sepsis rates, which indicate a close interdependence of movements in the mortality from erysipelas, puerperal fever, and scarlet fever, an interdependence which was pointed out 50 years ago by Dr. G. B. Longstaffe in a paper read before the Epidemiological Society. There are no reliable figures available as to the percentage of sterile women, and the operations of birth control in reducing fertility is an unknown factor. Economic stress by increasing the proportion of unwilling mothers may prejudice the normal risk and excessive spacing of confinements may also increase the risk by bringing about conditions approximating to those of first confinements. The conclusion drawn from this statistical analysis is that the sustained rate of maternal mortality, in spite of improvements in the maternity service, is in general terms the result of the repression of natural fertility brought about by economic conditions, but the tentative character of the statistics is stressed and the need for more detailed records relating to the maternal state.

Disease Incidence.

The notifications of *enteric* showed an increase from 322 in 1927 to 580 in 1928, largely owing to the outbreak of paratyphoid B attributed to infected cream. There were 41 confirmed cases of *poliomyelitis*, of which 9 ended fatally. There were five more fatal unnotified cases of this disease. There were 83 confirmed cases of *encephalitis lethargica* of which 27, or 32 per cent., were fatal. There were 22 additional deaths from this disease amongst unnotified cases, in many of whom the post-encephalitic symptoms were not observed until years after the mild primary illness. The M.A.B. has now provided 50 beds for persons over the ages of 16 suffering from post-encephalitic symptoms. *Influenza* caused 590 deaths as compared with 1815 in 1927, but during the last weeks of 1928 there were signs of an epidemic in the north which later became general, and in the first quarter of 1929 there were more deaths from influenza than in any first quarter since the great epidemic of 1918. *Acute rheumatism* under 16 is now notifiable in Holborn as well as in Kensington and Paddington. A comparison of the mortality from acute rheumatism in various groups of boroughs lends no support to the effect of social conditions in the causation of this disease.

Tuberculosis.

There has been practically no decrease in the mortality from pulmonary tuberculosis in London during the past three years. The experimental scheme, begun in 1926, by which the tuberculosis dispensaries could obtain artificial light treatment at certain hospitals and centres, was very little used by the tuberculosis officers of the 10 boroughs concerned, and further experience confirms the view expressed in last year's report that the best results are obtained when light treatment is given as an addition to the fresh air, good food, and regular régime provided in a residential institution in the country. The present scheme is therefore to be dropped. The scheme for boarding out children who are contacts with advanced pulmonary tuberculosis has been continued; 140 children were accepted and 52 were being boarded out at the end of the year.

Underground Rooms.

Existing legislation for the control of underground rooms has been directed almost exclusively to the regulation of such as sleeping-places, but Dr. Menzies points out that the use of basement dwellings as living rooms is particularly injurious to the health of the women and children, who mainly occupy them during the daytime and that there is no statutory power to close only part of a house. The council is therefore considering the promotion of further legislation to deal with the whole problem of underground rooms.

Milk.

During 1928 the biological examination of 1605 samples of milk from 40 counties was completed and 148, or 8·9 per cent., were found to be tuberculous. As the result of following up by various county medical officers of health 66 tuberculous cows were found and slaughtered under the Order. The difficulty of tracing is greatly increased by the bulking of the milk at country depôts prior to despatch and this is more than ever the case since the introduction of glass-lined tanks. For example, one of these containers may hold 3000 gallons of milk, which may have come from 200 farms. On the one hand, the introduction of a single infected milk infects the whole of the tank; on the other hand, a massive dose of tubercle bacilli is diluted. The attention of the Ministry of Health has been drawn to this matter. Another point that has arisen out of milk examinations is that the guinea-pigs frequently die from an acute intercurrent infection. Such cases have been reported to the authorities responsible for supervising the farms and have been found useful as a lever for the removal of insanitary conditions on the farm. In 1888 there were 738 licensed cowhouses in the county. In December, 1928, there were only 55, chiefly in the rural districts of Woolwich and in Stepney and Bethnal Green, where the considerable Jewish population, from religious motives, are always anxious to obtain fresh raw milk. In the case of the imported milk for the year ended June 30th, 1928, 7·6 of the samples were tuberculous and 16·9 per cent. of the guinea-pigs died from intercurrent infection, whilst in the case of the milk produced in London 6·7 per cent. of the milk samples were tuberculous and 7·5 per cent. of the guinea-pigs died from intercurrent infection, so that the comparison is in favour of the London-produced milk. The description of the powers wielded under the various Milk Acts by the L.C.C. and the boroughs respectively appears to be dual responsibility at its worst.

Venereal Diseases.

The number of attendances under the V.D. scheme per new V.D. case shows another great increase, and the number of non-venereal cases attending the clinics has increased from 2300 in 1917 to 10,164 in 1927, and 9595 in 1928.

A New Hospital.

Dr. Menzies mentions that the rapid growth of the population on the Becontree Estate has created a need for hospital accommodation and that the trustees of King Edward's Hospital Fund and the Ministry of Health have each agreed to contribute £10,000 towards the capital cost if an equal amount is subscribed from other sources and the details of the scheme are satisfactory.

MENTAL HOSPITAL REPORTS.

THE 116th annual report of the *Royal Edinburgh Hospital, Morningside*, is illustrated by two line drawings of the Jordanburn Nerve Hospital and the out-patient department, and opens with a historical retrospect and survey of psychology in social life.
